Formulas relating fluid flow and mechanical power follow. These formulas supplement the general force, torque, speed, and power formulas of mechanical systems.

$$F = P \times A$$

$$A = 0.7854 \times d^2$$

$$hp = 0.000583q \times \text{pressure in lb}_f/\text{in.}^2$$

$$1 \text{ gallon of fluid flow/min at } 1 \text{ lb}_f/\text{in.}^2 \text{ pressure} = 0.000582 \text{ hp.}$$

For rotary outputs,

$$hp = \text{torque} \times \text{rpm}/63,025$$

where torque is in lb-in. (Theoretical hp output must be multiplied by the efficiency of the hydraulic circuits to determine actual output.)

In the preceding equations,

$$P = \text{pressure in lb}_f/\text{in.}^2$$

$$A = \text{piston area in in.}^2$$

$$F = \text{force in lb}$$

$$q = \text{fluid flow in gallons/min}$$

$$d = \text{piston diameter in inches}$$

Hydraulic and Pneumatic Control Systems.—Control systems for hydraulic and pneumatic circuits are more mature than those for electromechanical systems because they have been developed over many more years. Hydraulic components are available at moderate prices from many sources. Although their design is complex, application and servicing of these systems are usually more straightforward than with electromechanical systems.

Electromechanical and hydraulic/pneumatic systems may be analyzed by similar means. The mathematical requirements for accuracy and stability are analogous, as are most performance features, although nonlinearities are caused by different physical attributes. Nonlinear friction, backlash, and voltage and current limiting are common to both types of system, but hydraulic/pneumatic systems also have the behavior characteristics of fluid-driven systems such as thermal effects and fluid flow dynamics including turbulence, leakage caused by imperfect seals, and contamination.

Both control types require overhead equipment that does not affect performance but adds to overall cost and complexity. For instance, electromechanical systems require electrical power sources and power control components, voltage regulators, fuses and circuit breakers, relays and switches, connectors, wiring and related devices. Hydraulic/pneumatic sys-

tems require fluid stored under pressure, motor-driven pumps or compressors, valves, pressure regulators/limiters, piping and fasteners, as well as hydraulic/pneumatic motors and cylinders. Frequently, the optimum system is selected on the basis of overhead equipment already available.

Electromechanical systems are generally slower and heavier than hydraulic systems and less suited to controlling heavy loads. The bandwidths of hydraulic control systems can respond to input signals of well over 100 Hz as easily as an electromechanical system can respond to, say, 10 to 20 Hz. Hydraulic systems can drive very high torque loads without intermediate transmissions such as the gear trains often used with electromechanical systems. Also, hydraulic/pneumatic systems using servo valves and piston/cylinder arrangements are inherently suited to linear motion operation, whereas electromechanical controls based on conventional electrical machines are more naturally suited to driving rotational loads.

Until recently, electromechanical systems were limited to system bandwidths of about 10 Hz, with power outputs of a few hundred watts. However, their capabilities have now been sharply extended through the use of rare-earth motor magnets having much higher energies than earlier designs. Similarly, semiconductor power components deliver much higher output power at lower prices than earlier equipment. Electromechanical control systems are now suited to applications of more than 100 hp with bandwidths up to 40 Hz and sometimes up to 100 Hz.

Although much depends on the specific design, the edge in reliability, even for high-power, fast-response needs, is shifting toward electromechanical systems. Basically, there are more things that can go wrong in hydraulic/pneumatic systems, as indicated by the shift to more electrical systems in aircraft.

Hydraulic Control Systems.—Using essentially incompressible fluid, hydraulic systems are suited to a wide range of applications, whereas pneumatic power is generally limited to simpler uses. In Fig. 2 are shown the essential features of a simple linear hydraulic control system and a comparable system for driving a rotating load.

Fig. 2. (left) A Simple Linear Hydraulic Control System in Which the Load Force Returns the Piston and (right) a Comparable System for Driving a Rotating Load

Hydraulic controls of the type shown have fast response and very high load capacities. In a linear actuator, for example, each lb/in^2 of system pressure acts against the area of the piston to generate the force applied. Hydraulic pressures of up to $3000 \text{ lb}/\text{in}^2$ are readily obtained from hydraulic pumps, so that cylinders can exert forces of hundreds of tons without the need for speed-reducing transmission systems to increase the force. The hydraulic fluid distributes heat, so it helps cool the system.

Systems similar to those in Fig. 2 can be operated in open- or closed-loop modes. Open-loop operation can be controlled by programming units that initiate each step by operating relays, limit switches, solenoid valves, and other components to generate the forces over

the required travel ranges. Auxiliary components are used to ensure safe operation and make such systems flexible and reliable, as shown in Fig. 3.

Fig. 3. Some of the Auxiliary Components Used in a Practical Hydraulic System

In the simplest mode, whether open- or closed-loop, hydraulic system operation may be discontinuous or proportional. Discontinuous operation, sometimes called bang-bang, or on-off, works well, is widely used in low- to medium-accuracy systems, and is easy to maintain. In this closed-loop mode, accuracy is limited; if the response to error is set too high, the system will oscillate between on-off modes, with average output at about the desired value. This oscillation, however, can be noisy, introduces system transients, and may cause rapid wear of system components.

Another factor to be considered in on-off systems is the shock caused by sudden opening and closing of high-pressure valves, which introduce transient pulses in the fluid flow and can cause high stresses in components. These problems can be addressed by the use of pressure-limiting relief valves and other units.

Proportional Control Systems.—Where the highest accuracy is required, perhaps in two directions, and with aiding or opposing forces or torques, a more sophisticated proportional control, closed-loop system is preferred. As shown in Fig. 4, the amplifier and electric servomotor used in electromechanical closed-loop systems is replaced in the closed-loop hydraulic system by an electronically controlled servo-valve. In its simplest form, the valve uses a linear motor to position the spool that determines the flow path for the hydraulic fluid. In some designs, the linear motor may be driven by a solenoid against a bias spring on the valve spool. In other arrangements, the motor may be a bidirectional unit that permits a fluid flow depending on the polarity and amplitude of the voltage supplied to the motor.

Fig. 4.

Such designs can be used in proportional control systems to achieve smooth operation and minimum nonlinearities, and will give the maximum accuracy required by the best machine tool applications. Where very high power must be controlled, use is often made of a two-stage valve in which the output from the first stage is used to drive the second-stage valve, as shown in Fig. 5.

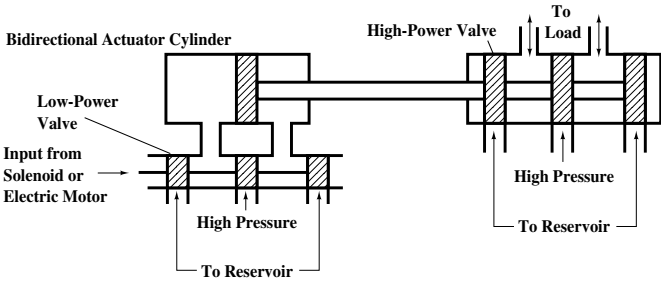

Fig. 5. Two-Stage Valve for Large-Power Control from a Low-Power Input

Electronic Controls.—An error-sensing electronic amplifier drives the solenoid motor of Fig. 5, which provides automatic output correction in a closed-loop system. The input is an ideal place to introduce electrical control features, adding greatly to the versatility of the control system. The electronic amplifier can provide the necessary driving power using pulse-width modulation as required, for minimum heating. The output can respond to signals in the low-microvolt range.

A major decision is whether to use analog or digital control. Although analog units are simple, they are much less versatile than their digital counterparts. Digital systems can be readjusted for total travel, speed, and acceleration by simple reprogramming. Use of appropriate feedback sensors can match accuracy to any production requirement, and a single digital system can be easily adapted to a great variety of similar applications. This adaptability is an important cost-saving feature for moderate-sized production runs. Modern microprocessors can integrate the operation of sets of systems.

Because nonlinearities and small incremental motions are easy to implement, digital systems are capable of very smooth acceleration, which avoids damaging shocks and induced leaks, and enhances reliability so that seals and hose connections last longer. The accuracy of digital control systems depends on transducer availability, and a full range of such devices has been developed and is now available.

Other features of digital controls are their capacity for self-calibration, easy digital read-out, and periodic self-compensation. For example, it is easy to incorporate backlash compensation. Inaccuracies can be corrected by using lookup tables that may themselves be updated as necessary. Digital outputs can be used as part of an inspection plan, to indicate need for tool changing, adjustment or sharpening, or for automatic record keeping. Despite continuing improvements in analog systems, digital control of hydraulic systems is favored in large plants.

Pneumatic Systems.—Hydraulic systems transmit power by means of the flow of an essentially incompressible fluid. Pneumatic systems use a highly compressible gas. For this reason, a pneumatic system is slower in responding to loads, especially sudden output loads, than a hydraulic system. Similarly, torque or force requires time and output motion to build up. Response to sudden output loads shows initial overshoot. Much more complex networks or other damping means are required to develop stable response in closed-loop systems. On the other hand, there are no harmful shock waves analogous to the transients that can occur in hydraulic systems, and pneumatic system components last comparatively longer.

Notwithstanding their performance deficiencies, pneumatic systems have numerous desirable features. Pneumatic systems avoid some fire hazards compared with the most preferred hydraulic fluids. Air can be vented to the atmosphere so a flow line only is needed, reducing the complexity, cost, and weight of the overall system. Pneumatic lines,

couplings, and fittings are lighter than their hydraulic counterparts, often a significant advantage. The gaseous medium also is lighter than hydraulic fluid, and pneumatic systems are usually easier to clean, assemble, and generally maintain. Fluid viscosity and its temperature variations are virtually negligible with pneumatic systems.

Among drawbacks with pneumatics are that lubrication must be carefully designed in, and more power is needed to achieve a desired pressure when the fluid medium is a compressible gas. Gas under high pressure can cause an explosion if its storage tank is damaged, so storage must have substantial safety margins. Gas compressibility makes pneumatic systems 1 or 2 orders of magnitude slower than hydraulic systems.

The low stiffness of pneumatic systems is another indicator of the long response time. Resonances occur between the compressible gas and equivalent system inertias at lower frequencies. Even the relatively low speed of sound in connecting lines contributes to response delay, adding to the difficulty of closed-loop stabilization. Fortunately, it is possible to construct pneumatic analogs to electrical networks to simplify stabilization at the exact point of the delays. Such pneumatic stabilizing means are commercially available and are important elements of closed-loop pneumatic control systems.

In contrast with hydraulic systems, where speed may be controlled by varying pump output, pneumatic system control is almost exclusively by valves, which control the flow from a pneumatic accumulator or pressure source. The pressure is maintained between limits by an intermittently operated pump. Low-pressure outlet ports must be large enough to accommodate the high volume of the expanded gas. In Fig. 6 is shown a simplified system for closed-loop position control applied to an air cylinder, in which static accuracy is controlled by the position sensor. Proper design requires a good theoretical analysis and attention to practical design if good, stable, closed-loop response is to be achieved.

Fig. 6. A Pneumatic Closed-Loop Linear Control System

O-RINGS

An O-ring is a one-piece molded elastomeric seal with a circular cross-section that seals by distortion of its resilient elastic compound. Dimensions of O-rings are given in ANSI/SAE AS568A, Aerospace Size Standard for O-rings. The standard ring sizes have been assigned identifying dash numbers that, in conjunction with the compound (ring material), completely specifies the ring. Although the ring sizes are standardized, ANSI/SAE AS568A does not cover the compounds used in making the rings; thus, different manufacturers will use different designations to identify various ring compounds. For example, 230-8307 represents a standard O-ring of size 230 (2.484 in. ID by 0.139 in. width) made with compound 8307, a general-purpose nitrile compound. O-ring material properties are discussed at the end of this section.

When properly installed in a groove, an O-ring is normally slightly deformed so that the naturally round cross-section is squeezed diametrically out of round prior to the application of pressure. This compression ensures that under static conditions, the ring is in contact with the inner and outer walls enclosing it, with the resiliency of the rubber providing a zero-pressure seal. When pressure is applied, it tends to force the O-ring across the groove, causing the ring to further deform and flow up to the fluid passage and seal it against leakage, as in Fig. 1(a). As additional pressure is applied, the O-ring deforms into a D shape, as in Fig. 1(b). If the clearance gap between the sealing surface and the groove corners is too large or if the pressure exceeds the deformation limits of the O-ring material (compound), the O-ring will extrude into the clearance gap, reducing the effective life of the seal. For very low-pressure static applications, the effectiveness of the seal can be improved by using a softer durometer compound or by increasing the initial squeeze on the ring, but at higher pressures, the additional squeeze may reduce the ring's dynamic sealing ability, increase friction, and shorten ring life.

Fig. 1.

The initial diametral squeeze of the ring is very important in the success of an O-ring application. The squeeze is the difference between the ring width W and the gland depth F (Fig. 2) and has a great effect on the sealing ability and life of an O-ring application.

Fig. 2. Groove and Ring Details

The ideal squeeze varies according to the ring cross-section, with the average being about 20 per cent, i.e., the ring's cross-section W is about 20 per cent greater than the gland depth F (groove depth plus clearance gap). The groove width is normally about 1.5 times larger than the ring width W . When installed, an O-ring compresses slightly and distorts into the free space within the groove. Additional expansion or swelling may also occur due to contact of the ring with fluid or heat. The groove must be large enough to accommodate the maximum expansion of the ring or the ring may extrude into the clearance gap or rupture the assembly. In a dynamic application, the extruded ring material will quickly wear and fray, severely limiting seal life.

To prevent O-ring extrusion or to correct an O-ring application, reduce the clearance gap by modifying the dimensions of the system, reduce the system operating pressure, install antiextrusion backup rings in the groove with the O-ring, as in Fig. 3, or use a harder O-ring compound. A harder compound may result in higher friction and a greater tendency of the seal to leak at low pressures. Backup rings, frequently made of leather, Teflon, metal, phenolic, hard rubber, and other hard materials, prevent extrusion and nibbling where large clearance gaps and high pressure are necessary.

Fig. 3. Preferred Use of Backup Washers

The most effective and reliable sealing is generally provided by using the diametrical clearances given in manufacturers' literature. However, the information in Table 1 may be used to estimate the gland depth (groove depth plus radial clearance) required in O-ring applications. The radial clearance used (radial clearance equals one-half the diametrical clearance) also depends on the system pressure, the ring compound and hardness, and specific details of the application.

Table 1. Gland Depth for O-Ring Applications

Standard O-Ring Cross-Sectional Diameter (in.)	Gland Depth (in.)	
	Reciprocating Seals	Static Seals
0.070	0.055 to 0.057	0.050 to 0.052
0.103	0.088 to 0.090	0.081 to 0.083
0.139	0.121 to 0.123	0.111 to 0.113
0.210	0.185 to 0.188	0.170 to 0.173
0.275	0.237 to 0.240	0.226 to 0.229

Source: Auburn Manufacturing Co. When possible, use manufacturer recommendations for clearance gaps and groove depth.

Fig. 4 indicates conditions where O-ring seals may be used, depending on the fluid pressure and the O-ring hardness. If the conditions of use fall to the right of the curve, extrusion of the O-ring into the surrounding clearance gap will occur, greatly reducing the life of the ring. If conditions fall to the left of the curve, no extrusion of the ring will occur, and the ring may be used under these conditions. For example, in an O-ring application with a 0.004-in. diametrical clearance and 2500-psi pressure, extrusion will occur with a 70 durometer O-ring but not with an 80 durometer O-ring. As the graph indicates, high-pressure applications require lower clearances and harder O-rings for effective sealing.

Fig. 4. Extrusion Potential of O-Rings as a Function of Hardness and Clearance

Recommended groove width, clearance dimensions, and bottom-of-groove radius for O-ring numbers up to 475 (25.940-in. ID by 0.275-in. width) can be found using Table 2 in conjunction with Fig. 5. In general, except for ring cross-sections smaller than $\frac{1}{16}$ in., the groove width is approximately $1.5W$, where W is the ring cross-sectional diameter. Straight-sided grooves are best for preventing extrusion of the ring or nibbling; however, for low-pressure applications (less than 1500 psi) sloped sides with an angle up to 5° can be used to simplify machining of the groove. The groove surfaces should be free of burrs, nicks, or scratches. For static seals (i.e., no contact between the O-ring and any moving parts), the groove surfaces should have a maximum roughness of 32 to 63 $\mu\text{in. rms}$ for liquid-sealing applications and 16 to 32 $\mu\text{in. rms}$ for gaseous-sealing applications. In dynamic seals, relative motion exists between the O-ring and one or more parts and the maximum groove surface roughness should be 8 to 16 $\mu\text{in. rms}$ for sliding contact applications (reciprocating seals, for example) and 16 to 32 $\mu\text{in. rms}$ for rotary contact applications (rotating and oscillating seals).

In dynamic seal applications, the roughness of surfaces in contact with O-rings (bores, pistons, and shafts, for example) should be 8 to 16 $\mu\text{in. rms}$, without longitudinal or circumferential scratches. Surface finishes of less than 5 $\mu\text{in. rms}$ are too smooth to give a good seal life because they wipe too clean, causing the ring to wear against the housing in the absence of a lubricating film. The best-quality surfaces are honed, burnished, or hard chromium plated. Soft and stringy metals such as aluminum, brass, bronze, Monel, or free machining stainless steel should not be used in contact with moving seals. In static applica-

tions, O-ring contacting surfaces should have a maximum surface roughness of 64 to 125 $\mu\text{in. rms}$.

Table 2. Diametral Clearance and Groove Sizes for O-Ring Applications

ANSI/SAE AS568 Number	Tolerances		Diametral Clearance, D		Groove Width, G			Bottom of Groove Radius, R	
	A	B	Reciprocating & Static Seals	Rotary Seals	Backup Rigs				
					None	One	Two		
001	+0.001 -0.000	+0.000 -0.001	0.002 to 0.004	0.012 to 0.016	0.063	0.149	0.207	0.005 to 0.015	
002					0.073				
003					0.083				
004 to 012					0.094				
013 to 050	+0.002 -0.000	+0.000 -0.002	0.002 to 0.005	0.016 to 0.020	0.141	0.183	0.245	0.010 to 0.025

425 to 475	-0.000	-0.003	0.004 to 0.010		0.375	0.475	0.579		

Source: Auburn Manufacturing Co. All dimensions are in inches. Clearances listed are minimum and maximum values; standard groove widths may be reduced by about 10 per cent for use with ring compounds that free swell less than 15 per cent. Dimension A is the ID of any surface contacted by the outside circumference of the ring; B is the OD of any surface contacted by the inside circumference of the ring.

Fig. 5. Installation data for use with Table 2. Max and Min are maximum and minimum piston and bore diameters for O.D. and I.D., respectively.

The preferred bore materials are steel and cast iron, and pistons should be softer than the bore to avoid scratching them. The bore sections should be thick enough to resist expansion and contraction under pressure so that the radial clearance gap remains constant, reducing the chance of damage to the O-ring by extrusion and nibbling. Some compatibility problems may occur when O-rings are used with plastics parts because certain compounding ingredients may attack the plastics, causing crazing of the plastics surface.

O-rings are frequently used as driving belts in round bottom or V-grooves with light tension for low-power drive elements. Special compounds are available with high resistance to stress relaxation and fatigue for these applications. Best service is obtained in drive belt applications when the initial belt tension is between 80 and 200 psi and the initial installed stretch is between 8 and 25 per cent of the circumferential length. Most of the compounds used for drive belts operate best between 10 and 15 per cent stretch, although polyurethane has good service life when stretched as much as 20 to 25 per cent.

Table 3. Typical O-Ring Compounds

Nitrile	General-purpose compound for use with most petroleum oils, greases, gasoline, alcohols and glycols, LP gases, propane and butane fuels. Also for food service to resist vegetable and animal fats. Effective temperature range is about -40° to 250° F. Excellent compression set, tear and abrasion resistance, but poor resistance to ozone, sunlight and weather. Higher-temperature nitrile compounds with similar properties are also available.
Hydrogenated Nitrile	Similar to general-purpose nitrile compounds with improved high-temperature performance, resistance to aging, and petroleum product compatibility.
Polychloroprene (Neoprene)	General-purpose compound with low compression set and good resistance to elevated temperatures. Good resistance to sunlight, ozone, and weathering, and fair oil resistance. Frequently used for refrigerator gases such as Freon. Effective temperature range is about -40° to 250° F.
Ethylene Propylene	General-purpose compound with excellent resistance to polar fluids such as water, steam, ketones, and phosphate esters, and brake fluids, but not resistant to petroleum oils and solvents. Excellent resistance to ozone and flexing. Recommended for belt-drive applications. Continuous duty service in temperatures up to 250° F.
Silicon	Widest temperature range (-150° to 500° F) and best low-temperature flexibility of all elastomeric compounds. Not recommended for dynamic applications, due to low strength, or for use with most petroleum oils. Shrinkage characteristics similar to organic rubber, allowing existing molds to be used.
Polyurethane	Toughest of the elastomers used for O-rings, characterized by high tensile strength, excellent abrasion resistance, and tear strength. Compression set and heat resistance are inferior to nitrile. Suitable for hydraulic applications that anticipate abrasive contaminants and shock loads. Temperature service range of -65° to 212° F.
Fluorosilicone	Wide temperature range (-80° to 450° F) for continuous duty and excellent resistance to petroleum oils and fuels. Recommended for static applications only, due to limited strength and low abrasion resistance.
Polyacrylate	Heat resistance better than nitrile compounds, but inferior low temperature, compression set, and water resistance. Often used in power steering and transmission applications due to excellent resistance to oil, automatic transmission fluids, oxidation, and flex cracking. Temperature service range of -20° to 300° F.
Fluorocarbon (Viton)	General-purpose compound suitable for applications requiring resistance to aromatic or halogenated solvents or to high temperatures (-20° to 500° F with limited service to 600° F). Outstanding resistance to blended aromatic fuels, straight aromatics, and halogenated hydrocarbons and other petroleum products. Good resistance to strong acids (temperature range in acids -20° to 250° F), but not effective for use with very hot water, steam, and brake fluids.

Ring Materials.—Thousands of O-ring compounds have been formulated for specific applications. Some of the most common types of compounds and their typical applications are given in [Table 3](#). The Shore A durometer is the standard instrument used for measuring the hardness of elastomeric compounds. The softest O-rings are 50 and 60 Shore A and stretch more easily, exhibit lower breakout friction, seal better on rough surfaces, and need less clamping pressure than harder rings. For a given squeeze, the higher the durometer hardness of a ring, the greater the associated friction because a greater compressive force is exerted by hard rings than soft rings.

The most widely used rings are medium-hard O-rings with 70 Shore A hardness, which have the best wear resistance and frictional properties for running seals. Applications that involve oscillating or rotary motion frequently use 80 Shore A materials. Rings with a hardness above 85 Shore A often leak more because of less effective wiping action. These harder rings have a greater resistance to extrusion, but for small sizes may break easily during installation. O-ring hardness varies inversely with temperature, but when used for continuous service at high temperatures, the hardness may eventually increase after an initial softening of the compound.

O-ring compounds have thermal coefficients of expansion in the range of 7 to 20 times that of metal components, so shrinkage or expansion with temperature change can pose problems of leakage past the seal at low temperatures and excessive pressures at high temperatures when a ring is installed in a tight-fitting groove. Likewise, when an O-ring is immersed in a fluid, the compound usually absorbs some of the fluid and consequently increases in volume. Manufacturer's data give volumetric increase data for compounds completely immersed in various fluids. For confined rings (those with only a portion of the ring exposed to fluid), the size increase may be considerably lower than for rings completely immersed in fluid. Certain fluids can also cause ring shrinkage during "idle" periods, i.e., when the seal has a chance to dry out. If this shrinkage is more than 3 to 4 per cent, the seal may leak.

Excessive swelling due to fluid contact and high temperatures softens all compounds approximately 20 to 30 Shore A points from room temperature values and designs should anticipate the expected operating conditions. At low temperatures, swelling may be beneficial because fluid absorption may make the seal more flexible. However, the combination of low temperature and low pressure makes a seal particularly difficult to maintain. A soft compound should be used to provide a resilient seal at low temperatures. Below -65°F , only compounds formulated with silicone are useful; other compounds are simply too stiff, especially for use with air and other gases.

Compression set is another material property and a very important sealing factor. It is a measure of the shape memory of the material, that is, the ability to regain shape after being deformed. Compression set is a ratio, expressed as a percentage, of the unrecovered to original thickness of an O-ring compressed for a specified period of time between two heated plates and then released. O-rings with excessive compressive set will fail to maintain a good seal because, over time, the ring will be unable to exert the necessary compressive force (squeeze) on the enclosing walls. Swelling of the ring due to fluid contact tends to increase the squeeze and may partially compensate for the loss due to compression set. Generally, compression set varies by compound and ring cross-sectional diameter, and increases with the operating temperature.

ROLLED STEEL SECTIONS, WIRE, AND SHEET-METAL GAGES

Rolled Steel Sections

Lengths of Angles Bent to Circular Shape.—To calculate the length of an angle-iron used either inside or outside of a tank or smokestack, the following table of constants may be used: Assume, for example, that a stand-pipe, 20 feet inside diameter, is provided with a 3 by 3 by $\frac{3}{8}$ inch angle-iron on the inside at the top. The circumference of a circle 20 feet in diameter is 754 inches. From the table of constants, find the constant for a 3 by 3 by $\frac{3}{8}$ inch angle-iron, which is 4.319. The length of the angle then is $754 - 4.319 = 749.681$ inches. Should the angle be on the outside, add the constant instead of subtracting it; thus, $754 + 4.319 = 758.319$ inches.

Size of Angle	Const.	Size of Angle	Const.	Size of Angle	Const.
$\frac{1}{4} \times 2 \times 2$	2.879	$\frac{5}{16} \times 3 \times 3$	4.123	$\frac{1}{2} \times 5 \times 5$	6.804
$\frac{5}{16} \times 2 \times 2$	3.076	$\frac{3}{8} \times 3 \times 3$	4.319	$\frac{3}{8} \times 6 \times 6$	7.461
$\frac{3}{8} \times 2 \times 2$	3.272	$\frac{1}{2} \times 3 \times 3$	4.711	$\frac{1}{2} \times 6 \times 6$	7.854
$\frac{1}{4} \times 2\frac{1}{2} \times 2\frac{1}{2}$	3.403	$\frac{3}{8} \times 3\frac{1}{2} \times 3\frac{1}{2}$	4.843	$\frac{3}{4} \times 6 \times 6$	8.639
$\frac{5}{16} \times 2\frac{1}{2} \times 2\frac{1}{2}$	3.600	$\frac{1}{2} \times 3\frac{1}{2} \times 3\frac{1}{2}$	5.235	$\frac{1}{2} \times 8 \times 8$	9.949
$\frac{3}{8} \times 2\frac{1}{2} \times 2\frac{1}{2}$	3.796	$\frac{3}{8} \times 4 \times 4$	5.366	$\frac{3}{4} \times 8 \times 8$	10.734
$\frac{1}{2} \times 2\frac{1}{2} \times 2\frac{1}{2}$	4.188	$\frac{1}{2} \times 4 \times 4$	5.758	$1 \times 8 \times 8$	11.520
$\frac{1}{4} \times 3 \times 3$	3.926	$\frac{3}{8} \times 5 \times 5$	6.414

Standard Designations of Rolled Steel Shapes.—Through a joint effort, the American Iron and Steel Institute (AISI) and the American Institute of Steel Construction (AISC) have changed most of the designations for their hot-rolled structural steel shapes. The present designations, standard for steel producing and fabricating industries, should be used when designing, detailing, and ordering steel. The accompanying Table 1 compares the present designations with the previous descriptions.

Table 1. Hot-Rolled Structural Steel Shape Designations (AISI and AISC)

Present Designation	Type of Shape	Previous Designation
W 24 x 76	W shape	24 WF 76
W 14 x 26	W shape	14 B 26
S 24 x 100	S shape	24 I 100
M 8 x 18.5	M shape	8 M 18.5
M 10 x 9	M shape	10 JR 9.0
M 8 x 34.3	M shape	8 x 8 M 34.3
C 12 x 20.7	American Standard Channel	12 [20.7
MC 12 x 45	Miscellaneous Channel	12 x 4 [45.0
MC 12 x 10.6	Miscellaneous Channel	12 JR [10.6

Table 2d. Steel Wide-Flange Sections

Wide-flange sections are designated, in order, by a section letter, nominal depth of the member in inches, and the nominal weight in pounds per foot; thus:
W 8 × 67
 indicates a wide-flange section having a nominal depth of 8 inches, and a nominal weight per foot of 67 pounds. Actual geometry for each section can be obtained from the values below.

Structural sections are available in 6061-T6 aluminum alloy. Data supplied by The Aluminum Association.

Wire and Sheet-Metal Gages

The thicknesses of sheet metals and the diameters of wires conform to various gaging systems. These gage sizes are indicated by numbers, and the following tables give the decimal equivalents of the different gage numbers. Much confusion has resulted from the use of gage numbers, and in ordering materials it is preferable to give the exact dimensions in decimal fractions of an inch. While the dimensions thus specified should conform to the gage ordinarily used for a given class of material, any error in the specification due, for example, to the use of a table having "rounded off" or approximate equivalents, will be apparent to the manufacturer at the time the order is placed. Furthermore, the decimal method of indicating wire diameters and sheet metal thicknesses has the advantage of being self-explanatory, whereas arbitrary gage numbers are not. The decimal system of indicating gage sizes is now being used quite generally, and gage numbers are gradually being discarded. Unfortunately, there is considerable variation in the use of different gages. For example, a gage ordinarily used for copper, brass and other non-ferrous materials, may at times be used for steel, and vice versa. The gages specified in the following are the ones ordinarily employed for the materials mentioned, but there are some minor exceptions and variations in the different industries.

Wire Gages.—The wire gage system used by practically all of the steel producers in the United States is known by the name Steel Wire Gage or to distinguish it from the Standard Wire Gage (S.W.G.) used in Great Britain it is called the United States Steel Wire Gage. It is the same as the Washburn and Moen, American Steel and Wire Company, and Roebling Wire Gages. The name has the official sanction of the Bureau of Standards at Washington but is not legally effective. The only wire gage which has been recognized in Acts of Congress is the Birmingham Gage (also known as Stub's Iron Wire). The Birmingham Gage is, however, nearly obsolete in both the United States and Great Britain, where it originated. Copper and aluminum wires are specified in decimal fractions. They were formerly universally specified in the United States by the American or Brown & Sharpe Wire Gage. Music spring steel wire, one of the highest quality wires of several types used for mechanical springs, is specified by the piano or music wire gage.

In Great Britain one wire gage has been legalized. This is called the Standard Wire Gage (S.W.G.), formerly called Imperial Wire Gage.

Gages for Rods.—Steel wire rod sizes are designated by fractional or decimal parts of an inch and by the gage numbers of the United States Steel Wire Gage. Copper and aluminum rods are specified by decimal fractions and fractions. Drill rod may be specified in decimal fractions but in the carbon and alloy tool steel grades may also be specified in the Stub's Steel Wire Gage and in the high-speed steel drill rod grade may be specified by the Morse Twist Drill Gage (Manufacturers' Standard Gage for Twist Drills). For gage numbers with corresponding decimal equivalents see the tables of American Standard Straight Shank Twist Drills, for example, page 856, and Table 5a on page 2525.

Gages for Wall Thicknesses of Tubing.—At one time the Birmingham or Stub's Iron Wire Gage was used to specify the wall thickness of the following classes of tubing: seamless brass, seamless copper, seamless steel, and aluminum. The Brown & Sharpe Wire Gage was used for brazed brass and brazed copper tubing. Wall thicknesses are now specified by decimal parts of an inch but the wall thickness of steel pressure tubes and steel mechanical tubing may be specified by the Birmingham or Stub's Iron Wire Gage. In Great Britain the Standard Wire Gage (S.W.G.) is used to specify the wall thickness of some kinds of steel tubes.

^a Also known as Washburn and Moen, American Steel and Wire Co. and Roebling Wire Gages. A greater selection of sizes is available and is specified by what are known as split gage numbers. They can be recognized by 1/2 fractions which follow the gage number; i.e., 4 1/2. The decimal equivalents of split gage numbers are in the Steel Products Manual entitled: *Wire and Rods, Carbon Steel* published by the American Iron and Steel Institute, Washington, DC.

Strength and Stiffness of Perforated Metals.—It is common practice to use perforated metals in equipment enclosures to provide cooling by the flow of air or fluids. If the perforated material is to serve also as a structural member, then calculations of stiffness and strength must be made that take into account the effect of the perforations on the strength of the panels.

The accompanying table provides equivalent or effective values of the yield strength S^* ; modulus of elasticity E^* ; and Poisson's ratio ν^* of perforated metals in terms of the values for solid material. The S^*/S and E^*/E ratios, given in the accompanying table for the standard round hole staggered pattern, can be used to determine the safety margins or deflections for perforated metal use as compared to the unperforated metal for any geometry or loading condition.

Perforated material has different strengths depending on the direction of loading; therefore, values of S^*/S in the table are given for the width (strongest) and length (weakest) directions. Also, the effective elastic constants are for plane stress conditions and apply to the in-plane loading of thin perforated sheets; the bending stiffness is greater. However, since most loading conditions involve a combination of bending and stretching, it is more convenient to use the same effective elastic constants for these combined loading conditions. The plane stress effective elastic constants given in the table can be conservatively used for all loading conditions.

Mechanical Properties of Materials Perforated with Round Holes in IPA Standard Staggered Hole Pattern

127	$\frac{7}{16}$	$\frac{5}{8}$	45	0.300	0.239	0.265	0.38
128	$\frac{1}{2}$	$1\frac{1}{16}$	47	0.273	0.214	0.230	0.39
129	$\frac{9}{16}$	$\frac{3}{4}$	51	0.250	0.192	0.205	0.42

Value in parentheses specifies holes per square inch instead of center distance. S^*/S = ratio of yield strength of perforated to unperforated material; E^*/E = ratio of modulus of elasticity of perforated to unperforated material; ν^* = Poisson's ratio for given percentage of open area.

IPA is Industrial Perforators Association.

Sheet-Metal Gages.—Thicknesses of steel sheets given in [Table 2](#) are based upon a weight of 41.82 pounds per square foot per inch of thickness, which is known as the Manufacturers' Standard Gage for Sheet Steel. This gage differs from the older United States Standard Gage for iron and steel sheets and plates, established by Congress in 1893, based upon a weight of 40 pounds per square foot per inch of thickness which is the weight of wrought-iron plate.

^a Manufacturers' Standard Gage for Sheet Steel

^b B.G. is the Birmingham Gage for sheets and hoops.

The United States Standard Gage (not shown above) for iron and steel sheets and plates was established by Congress in 1893 and was primarily a *weight* gage rather than a thickness gage. The equivalent thicknesses were derived from the weight of wrought iron. The weight per cubic foot was taken at 480 pounds, thus making the weight of a plate 12 inches square and 1 inch thick, 40 pounds. In converting weight to equivalent thickness, gage tables formerly published contained thicknesses equivalent to the basic weights just mentioned. For example, a No. 3 U.S. gage represents a wrought-iron plate having a weight of 10 pounds per square foot; hence, if the weight per square foot per inch thick is 40 pounds, the plate thickness for a No. 3 gage = $10 \div 40 = 0.25$ inch, which was the original thickness equivalent for this gage number. Because this and the other thickness equivalents were derived from the weight of wrought iron, they are not correct for steel.

Zinc sheets are usually ordered by specifying decimal thickness although a zinc gage exists and is shown in [Table 2](#).

Most sheet-metal products in Great Britain are specified by the British Standard Wire Gage (Imperial Wire Gage). Black iron and steel sheet and hooping, and galvanized flat and corrugated steel sheet, however, are specified by the Birmingham Gage (B.G.), which was legalized in 1914, and are also shown in [Table 2](#). This Birmingham Gage should not be confused with the Birmingham or Stub's Iron Wire Gage mentioned previously.

Thicknesses of aluminum, copper, and copper-base alloys were formerly designated by the American or Brown & Sharpe Wire Gage but now are specified in decimals or fractions of an inch. American National Standard B32.1-1952 (R1988) entitled Preferred Thicknesses for Uncoated Thin Flat Metals (see accompanying [Table 3](#)) gives thicknesses that are based on the 20- and 40-series of preferred numbers in American National Standard Preferred Numbers — ANSI Z17.1 (see Handbook page [689](#)) and are applicable to uncoated, thin, flat metals and alloys. Each number of the 20-series is approximately 12 percent greater than the next smaller one and each number of the 40-series is approximately 6 percent greater than the next smaller one.

The American National Standard ANSI B32.1-1952 (R1994) lists preferred thicknesses that are based on the 20- and 40-series of preferred numbers and states that those based on the 40-series should provide adequate coverage. However, where intermediate thicknesses are required, the Standard recommends that thicknesses be based on the 80-series of preferred numbers (see Handbook page [689](#)).

Thicknesses for copper and copper-base alloy flat products below $\frac{1}{4}$ inch thick are specified by the 20-series of American National Standard Preferred Numbers given in ANSI B32.1. Although the table in ANSI B32.1 gives only the 20- and 40-series of numbers, it states that when intermediate thicknesses are required they should be selected from thicknesses based on the 80-series of numbers (see Handbook page [689](#)).

Metric Sizes for Flat Metal Products.—American National Standard B32.3M-1984, (R1994) establishes a preferred series of metric thicknesses, widths, and lengths for flat metal products of rectangular cross section; the thickness and width values are also applicable to base metals that may be coated in later operations. [Table 4a](#) lists the preferred thicknesses; [Table 4b](#) lists the preferred widths. Whenever possible, the Preferred Thick-

ness and Preferred Widths values should be used, with the Second or Third Preference chosen only if no suitable Preferred size is available. Since not all metals and grades are produced in each of the sizes given in Tables 4a and 4b, producers or distributors should be consulted to determine a particular product and size combination's availability.

PIPE AND PIPE FITTINGS

Wrought Steel Pipe.—ANSI/ASME B36.10M-1995 covers dimensions of welded and seamless wrought steel pipe, for high or low temperatures or pressures.

The word *pipe* as distinguished from *tube* is used to apply to tubular products of dimensions commonly used for pipelines and piping systems. Pipe dimensions of sizes 12 inches and smaller have outside diameters numerically larger than the corresponding nominal sizes whereas outside diameters of tubes are identical to nominal sizes.

Size: The size of all pipe is identified by the nominal pipe size. The manufacture of pipe in the nominal sizes of $\frac{1}{8}$ inch to 12 inches, inclusive, is based on a standardized outside diameter (OD). This OD was originally selected so that pipe with a standard OD and having a wall thickness which was typical of the period would have an inside diameter (ID) approximately equal to the nominal size. Although there is now no such relation between the existing standard thicknesses, ODs and nominal sizes, these nominal sizes and standard ODs continue in use as “standard.”

The manufacture of pipe in nominal sizes of 14-inch OD and larger proceeds on the basis of an OD corresponding to the nominal size.

Weight: The nominal weights of steel pipe are calculated values and are tabulated in [Table 1](#). They are based on the following formula:

$$W_{pe} = 10.68(D - t)t$$

where W_{pe} = nominal plain end weight to the nearest 0.01 lb/ft.

D = outside diameter to the nearest 0.001 inch

t = specified wall thickness rounded to the nearest 0.001 inch

Wall thickness: The nominal wall thicknesses are given in [Table 1](#) which also indicates the wall thicknesses in API Standard 5L.

The wall thickness designations “Standard,” “Extra-Strong,” and “Double Extra-Strong” have been commercially used designations for many years. The Schedule Numbers were subsequently added as a convenient designation for use in ordering pipe. “Standard” and Schedule 40 are identical for nominal pipe sizes up to 10 inches, inclusive. All larger sizes of “Standard” have $\frac{3}{8}$ -inch wall thickness. “Extra-Strong” and Schedule 80 are identical for nominal pipe sizes up to 8 inch, inclusive. All larger sizes of “Extra-Strong” have $\frac{1}{2}$ -inch-wall thickness.

Wall Thickness Selection: When the selection of wall thickness depends primarily on capacity to resist internal pressure under given conditions, the designer shall compute the exact value of wall thickness suitable for conditions for which the pipe is required as prescribed in the “ASME Boiler and Pressure Vessel Code,” “ANSI B31 Code for Pressure Piping,” or other similar codes, whichever governs the construction. A thickness can then be selected from [Table 1](#) to suit the value computed to fulfill the conditions for which the pipe is desired.

Metric Weights and Mass: Standard SI metric dimensions in millimeters for outside diameters and wall thicknesses may be found by multiplying the inch dimensions by 25.4. Outside diameters converted from those shown in [Table 1](#) should be rounded to the nearest 0.1 mm and wall thicknesses to the nearest 0.01 mm.

The following formula may be used to calculate the SI metric plain end mass in kg/m using the converted metric diameters and thicknesses:

$$W_{pe} = 0.02466(D - t)t$$

where W_{pe} = nominal plain end mass rounded to the nearest 0.01 kg/m.

D = outside diameter to the nearest 0.1 mm for sizes shown in [Table 1](#).

t = specified wall thickness rounded to the nearest 0.01 mm.

To obtain volume of flow at any other velocity, multiply values in table by velocity in feet per minute.

Plastics Pipe.—Shortly after World War II, plastics pipe became an acceptable substitute, under certain service conditions, for other piping materials. Now, however, plastics pipe is specified on the basis of its own special capabilities and limitations. The largest volume of application has been for water piping systems.

Besides being light in weight, plastics pipe performs well in resisting deterioration from corrosive or caustic fluids. Even if the fluid borne is harmless, the chemical resistance of plastics pipe offers protection against a harmful exterior environment, such as when buried in a corrosive soil.

Generally, plastics pipe is limited by its temperature and pressure capacities. The higher the operating pressure of the pipe system, the less will be its temperature capability. The reverse is true, also. Since it is formed from organic resins, plastics pipe will burn. For various piping compositions, ignition temperatures vary from 700° to 800°F (370° to 430°C).

The following are accepted methods for joining plastics pipe:

Solvent Welding is usually accomplished by brushing a solvent cement on the end of the length of pipe and into the socket end of a fitting or the flange of the next pipe section. A chemical weld then joins and seals the pipe after connection.

Threading is a procedure not recommended for thin-walled plastics pipe or for specific grades of plastics. During connection of thicker-walled pipe, strap wrenches are used to avoid damaging and weakening the plastics.

Heat Fusion involves the use of heated air and plastics filler rods to weld plastics pipe assemblies. A properly welded joint can have a tensile strength equal to 90 percent that of the pipe material.

Elastomeric Sealing is used with bell-end piping. It is a recommended procedure for large diameter piping and for underground installations. The joints are set quickly and have good pressure capabilities.

The nominal weights of plastics pipe given in this table are based on an empirically chosen material density of 1.00 g/cm³. The nominal unit weight for a specific plastics pipe formulation can be

obtained by multiplying the weight values from the table by the density in g/cm^3 or by the specific gravity of the particular plastics composition.

The following are ranges of density factors for various plastics pipe materials: PE, 0.93 to 0.96; PVC, 1.35 to 1.40; CPVC, 1.55; ABS, 1.04 to 1.08; SR, 1.05; PB, 0.91 to 0.92; and PP, 0.91. For meanings of abbreviations see [Table 6](#).

Information supplied by the Plastics Pipe Institute.

Insert Fitting is particularly useful for PE and PB pipe. For joining pipe sections, insert fittings are pushed into the pipe and secured by stainless steel clamps.

Transition Fitting involves specially designed connectors to join plastic pipe with other materials, such as cast iron, steel, copper, clay, and concrete.

Plastic pipe can be specified by means of Schedules 40, 80, and 120, which conform dimensionally to metal pipe, or through a Standard Dimension Ratio (SDR). The SDR is a rounded value obtained by dividing the average outside diameter of the pipe by the wall thickness. Within an individual SDR series of pipe, pressure ratings are uniform, regardless of pipe diameter.

[Table 5](#) provides the weights and dimensions for Schedule 40 and 80 thermoplastic pipe, [Table 6](#) gives properties of plastics pipe, [Table 7](#) gives maximum non-shock operating pressures for several varieties of Schedule 40 and 80 plastics pipe at 73°F, and [Table 8](#) gives correction factors to pressure ratings for elevated temperatures.

Table 6. General Properties and Uses of Plastic Pipe

Plastic Pipe Material	Properties	Common Uses	Operating Temperature ^a		Joining Methods
			With Pressure	Without Pressure	
ABS (Acrylonitrilebutadiene styrene)	Rigid; excellent impact strength at low temperatures; maintains rigidity at higher temperatures.	Water, Drain, Waste, Vent, Sewage.	100°F (38°C)	180°F (82°C)	Solvent cement, Threading, Transition fitting.
PE (Polyethylene)	Flexible; excellent impact strength; good performance at low temperatures.	Water, Gas, Chemical, Irrigation.	100°F (38°C)	180°F (82°C)	Heat fusion, Insert and Transition fitting.
PVC (Polyvinylchloride)	Rigid; fire self-extinguishing; high impact and tensile strength.	Water, Gas, Sewage, Industrial process, Irrigation.	100°F (38°C)	180°F (82°C)	Solvent cement, Elastomeric seal, Mechanical coupling, Transition fitting.
CPVC (Chlorinated polyvinyl chloride)	Rigid; fire self-extinguishing; high impact and tensile strength.	Hot and cold water, Chemical.	180°F (82°C) at 100 psig (690kPa) for SDR-11		Solvent cement, Threading, Mechanical coupling, Transition fitting.
PB (Polybutylene)	Flexible; good performance at elevated temperatures.	Water, Gas, Irrigation.	180°F (82°C)	200°F (93°C)	Insert fitting, Heat fusion, Transition fitting.
PP (Polypropylene)	Rigid; very light; high chemical resistance, particularly to sulfur-bearing compounds.	Chemical waste and processing.	100°F (38°C)	180°F (82°C)	Mechanical coupling, Heat fusion, Threading.
SR (Styrene rubber plastic)	Rigid; moderate chemical resistance; fair impact strength.	Drainage, Septic fields.	150°F (66°C)	...	Solvent cement, Transition fitting, Elastomeric seal.

^aThe operating temperatures shows are general guide points. For specific operating temperature and pressure data for various grades of the types of plastic pipe given, please consult the pipe manufacturer or the Plastics Pipe Institute.

From information supplied by the Plastics Pipe Institute.

PIPE AND PIPE FITTINGS

8	160	...	250 ^b	NR
10	140	...	230	NR
12	130	...	230	NR

^a Recommended for intermittent drainage pressure not exceeding 20 psi.

^b 8-inch CPVC Tee, 90° Ell, and 45° Ell are rated at half the pressure shown.

ABS pressures refer to unthreaded pipe only.

For service at higher temperature, multiply the pressure obtained from this table by the correction factor from [Table 6](#).

NR is not recommended.

Table 8. Temperature-Correction Factors for Thermoplastic Piping Operating Pressures

280	NR	NR	NR	0.18

^a Recommended for intermittent drainage pressure not exceeding 20 psi.

NR = not recommended.

For more detailed information concerning the properties of a particular plastic pipe formulation, consult the pipe manufacturer or Plastics Pipe Institute, 1825 Connecticut Ave. NW, Washington, D.C. 20009.

Pipe and Tube Bending.—In bending a pipe or tube, the outer part of the bend is stretched and the inner section compressed, and as the result of opposite and unequal stresses, the pipe or tube tends to flatten or collapse. To prevent such distortion, the common practice is to support the wall of the pipe or tube in some manner during the bending operation. This support may be in the form of a filling material, or, when a bending machine or fixture is used, an internal mandrel or ball-shaped member may support the inner wall when required.

If a filling material is used, it is melted and poured into the pipe or tube. Many filler materials made up from combinations of bismuth, lead, tin, and cadmium, with melting points around 160 degrees F are commercially available. With this material, tubes having very thin walls have been bent to small radii. The metal filler conforms to the inside of the tube so closely that the tube can be bent just as though it were a solid rod. The filler is removed readily by melting.

This method has been applied to the bending of copper, brass, duralumin, plain steel, and stainless steel tubes with uniform success. Tubes plated with chromium or nickel can often be bent without danger of the plate flaking off. Other filling materials such as resin, tar, lead, and dry sand have also been used.

Pipes are often bent to avoid the use of fittings, thus eliminating joints, providing a smooth unobstructed passage for fluids, and resulting in certain other advantages.

Minimum Radius: The safe minimum radius for a given diameter, material, and method of bending depends upon the thickness of the pipe wall, it being possible, for example, to bend extra heavy pipe to a smaller radius than pipe of standard weight. As a general rule, wrought iron or steel pipe of standard weight may readily be bent to a radius equal to five or six times the nominal pipe diameter. The minimum radius for standard weight pipe should, as a rule, be three and one-half to four times the diameter. It will be understood, however, that the minimum radius may vary considerably, depending upon the method of bending. Extra heavy pipe may be bent to radii varying from two and one-half times the diameter for smaller sizes to three and one-half to four times the diameter for larger sizes.

Rules for Finding Lengths of Bends: In determining the required length of a pipe or tube before bending, the lengths of the straight sections are, of course, added to the lengths required for the curved sections in order to make the proper allowance for bends. The following rules are for finding the lengths of the curved sections.

Length of 90-Degree Bend: To find the length of a 90-degree or right-angle bend, multiply the radius of the bend by 1.57. The radius is measured to the center of the pipe, or to a point midway between the inner and outer walls.

Length of 180-Degree Bend: Multiply the radius of the bend by 3.14.

Length of other than 90- or 180-Degree Bend: Multiply the radius of the bend by the included angle, and then multiply the product by the constant 0.01745. The result is the length of the curved section.

Definitions of Pipe Fittings.—The following definitions for various pipe fittings are given by the National Tube Co.:

Armstrong Joint: A two-bolt, flanged or lugged connection for high pressures. The ends of the pipes are peculiarly formed to properly hold a gutta-percha ring. It was originally made for cast-iron pipe. The two-bolt feature has much to commend it. There are various substitutes for this joint, many of which employ rubber in place of gutta-percha; others use more bolts in order to reduce the cost.

Bell and Spigot Joint: a) The usual term for the joint in cast-iron pipe. Each piece is made with an enlarged diameter or bell at one end into which the plain or spigot end of another piece is inserted when laying. The joint is then made tight by cement, oakum, lead, rubber or other suitable substance, which is driven in or calked into the bell and around the spigot. When a similar joint is made in wrought pipe by means of a cast bell (or hub), it is at times

called hub and spigot joint (poor usage). Matheson joint is the name applied to a similar joint in wrought pipe which has the bell formed from the pipe.

b) Applied to fittings or valves, means that one end of the run is a "bell," and the other end is a "spigot," similar to those used on regular cast-iron pipe.

Bonnet: a) A cover used to guide and enclose the tail end of a valve spindle.

b) A cap over the end of a pipe (poor usage).

Branch: The outlet or inlet of a fitting not in line with the run, but which may make any angle.

Branch Ell: a) Used to designate an elbow having a back outlet in line with one of the outlets of the "run." It is also called a heel outlet elbow.

b) Incorrectly used to designate side outlet or back outlet elbow.

Branch Pipe: A very general term used to signify a pipe either cast or wrought, that is equipped with one or more branches. Such pipes are used so frequently that they have acquired common names such as tees, crosses, side or back outlet elbows, manifolds, double-branch elbows, etc. The term branch pipe is generally restricted to such as do not conform to usual dimensions.

Branch Tee or Header: A tee having many side branches. (See *Manifold*.)

Bull Head Tee: A tee the branch of which is larger than the run.

Bushing: A pipe fitting for the purpose of connecting a pipe with a fitting of larger size, being a hollow plug with internal and external threads to suit the different diameters.

Card Weight Pipe: A term used to designate standard or full weight pipe, which is the Briggs' standard thickness of pipe.

Close Nipple: One the length of which is about twice the length of a standard pipe thread and is without any shoulder.

Coupling: A threaded sleeve used to connect two pipes. Commercial couplings are threaded inside to suit the exterior thread of the pipe. The term coupling is occasionally used to mean any jointing device and may be applied to either straight or reducing sizes.

Cross: A pipe fitting with four branches arranged in pairs, each pair on one axis, and the axes at right angles. When the outlets are otherwise arranged the fittings are branch pipes or specials.

Cross-over: A small fitting with a double offset, or shaped like the letter U with the ends turned out. It is only made in small sizes and used to pass the flow of one pipe past another when the pipes are in the same plane.

Cross-over Tee: A fitting made along lines similar to the cross-over, but having at one end two openings in a tee-head the plane of which is at right angles to the plane of the cross-over bend.

Cross Valve: a) A valve fitted on a transverse pipe so as to open communication at will between two parallel lines of piping. Much used in connection with oil and water pumping arrangements, especially on ship board.

b) Usually considered as an angle valve with a back outlet in the same plane as the other two openings.

Crotch: A fitting that has the general shape of the letter Y. Caution should be exercised not to confuse the crotch and wye.

Double-branch Elbow: A fitting that, in a manner, looks like a tee, or as if two elbows had been shaved and then placed together, forming a shape something like the letter Y or a crotch.

Double Sweep Tee: A tee made with easy curves between body and branch, i.e., the center of the curve between run and branch lies outside the body.

Drop Elbow: A small sized ell that is frequently used where gas is put into a building. These fittings have wings cast on each side. The wings have small countersunk holes so that they may be fastened by wood screws to a ceiling or wall or framing timbers.

Drop Tee: One having the same peculiar wings as the drop elbow.

Dry Joint: One made without gasket or packing or smear of any kind, as a ground joint.

Elbow (ELL): A fitting that makes an angle between adjacent pipes. The angle is always 90 degrees, unless another angle is stated. (See *Branch Ell*, *Service Ell*, and *Union Ell*.)

Extra Heavy: When applied to pipe, means pipe thicker than standard pipe; when applied to valves and fittings, indicates goods suitable for a working pressure of 250 pounds per square inch.

Header: A large pipe into which one set of boilers is connected by suitable nozzles or tees, or similar large pipes from which a number of smaller ones lead to consuming points. Headers are often used for other purposes—for heaters or in refrigeration work. Headers are essentially branch pipes with many outlets, which are usually parallel. Largely used for tubes of water-tube boilers.

Hydrostatic Joint: Used in large water mains, in which sheet lead is forced tightly into the bell of a pipe by means of the hydrostatic pressure of a liquid.

Kewanee Union: A patented pipe union having one pipe end of brass and the other of malleable iron, with a ring or nut of malleable iron, in which the arrangement and finish of the several parts is such as to provide a non-corrosive ball-and-socket joint at the junction of the pipe ends, and a non-corrosive connection between the ring and brass pipe end.

Lead Joint: a) Generally used to signify the connection between pipes which is made by pouring molten lead into the annular space between a bell and spigot, and then making the lead tight by calking.

b) Rarely used to mean the joint made by pressing the lead between adjacent pieces, as when a lead gasket is used between flanges.

Lead Wool: A material used in place of molten lead for making pipe joints. It is lead fiber, about as coarse as fine excelsior, and when made in a strand, it can be calked into the joints, making them very solid.

Line Pipe: Special brand of pipe that employs recessed and taper thread couplings, and usually greater length of thread than Briggs' standard. The pipe is also subjected to higher test.

Lip Union: a) A special form of union characterized by the lip that prevents the gasket from being squeezed into the pipe so as to obstruct the flow.

b) A ring union, unless flange is specified.

Manifold: a) A fitting with numerous branches used to convey fluids between a large pipe and several smaller pipes. (See *Branch Tee* or *Header*.)

b) A header for a coil.

Matheson Joint: A wrought pipe joint made by enlarging one end of the pipe to form a suitable lead recess, similar to the bell end of a cast-iron pipe, and which receives the male or spigot end of the next length. Practically the same style of a joint as used for cast-iron pipe.

Medium Pressure: When applied to valves and fittings, means suitable for a working pressure of from 125 to 175 pounds per square inch.

Needle Valve: A valve provided with a long tapering point in place of the ordinary valve disk. The tapering point permits fine graduation of the opening. At times called a needle point valve.

Nipple: A tubular pipe fitting usually threaded on both ends and under 12 inches in length. Pipe over 12 inches long is regarded as cut pipe. (See *Close Nipple*, *Short Nipple*, *Shoulder Nipple*, and *Space Nipple*.)

Reducer: a) A fitting having a larger size at one end than at the other. Some have tried to establish the term "increaser" — thinking of direction of flow — but this has been due to a misunderstanding of the trade custom of always giving the largest size of run of a fitting first; hence, all fittings having more than one size are reducers. They are always threaded inside, unless specified flanged or for some special joint.

b) Threaded type, made with abrupt reduction.

c) Flanged pattern with taper body.

d) Flanged eccentric pattern with taper body, but flanges at 90 degrees to one side of body.

e) Misapplied at times, to a reducing coupling.

Run: a) A length of pipe that is made of more than one piece of pipe.

b) The portion of any fitting having its ends "in line" or nearly so, in contradistinction to the branch or side opening, as of a tee. The two main openings of an ell also indicate its run, and when there is a third opening on an eli, the fitting is a "side outlet" or "back outlet" elbow, except that when all three openings are in one plane and the back outlet is in line with one of the run openings, the fitting is a "heel outlet elbow" or a "single sweep tee" or sometimes a "branch tee."

Rust Joint: Employed to secure rigid connection. The joint is made by packing an intervening space tightly with a stiff paste which oxidizes the iron, the whole rusting together and hardening into a solid mass. It generally cannot be separated except by destroying some of the pieces. One recipe is 80 pounds cast-iron borings or filings, 1 pound sal-ammoniac, 2 pounds flowers of sulphur, mixed to a paste with water.

Service Ell: An elbow having an outside thread on one end. Also known as street ell.

Service Pipe: A pipe connecting mains with a dwelling.

Service Tee: A tee having inside thread on one end and on branch, but outside thread on other end of run. Also known as street tee.

Short Nipple: One whose length is a little greater than that of two threaded lengths or somewhat longer than a close nipple. It always has some unthreaded portion between the two threads.

Shoulder Nipple: A nipple of any length, which has a portion of pipe between two pipe threads. As generally used, however, it is a nipple about halfway between the length of a close nipple and a short nipple.

Space Nipple: A nipple with a portion of pipe or shoulder between the two threads. It may be of any length long enough to allow a shoulder.

Standard Pressure: A term applied to valves and fittings suitable for a working steam pressure of 125 pounds per square inch.

Tee: A fitting, either cast or wrought, that has one side outlet at right angles to the run. A single outlet branch pipe. (See *Branch Tee or Header*, *Bull Head Tee*, *Cross-over Tee*, *Double Sweep Tee*, *Drop Tee*, *Service Tee*, and *Union Tee*.)

Union: The usual trade term for a device used to connect pipes. It commonly consists of three pieces which are, first, the thread end fitted with exterior and interior threads; second, the bottom end fitted with interior threads and a small exterior shoulder; and third, the ring which has an inside flange at one end while the other end has an inside thread like that on the exterior of the thread end. A gasket is placed between the thread and bottom ends, which are drawn together by the ring. Unions are very extensively used, because they permit of connections with little disturbance of the pipe positions.

Union Ell: An ell with a male or female union at one end.

Union Joint: A pipe coupling, usually threaded, which permits disconnection without disturbing other sections.

Union Tee: A tee with male or female union at connection on one end of run.

Wiped Joint: A lead joint in which the molten solder is poured upon the desired place, after scraping and fitting the parts together, and the joint is wiped up by hand with a moleskin or cloth pad while the metal is in a plastic condition.

Wye (Y): A fitting either cast or wrought that has one side outlet at any angle other than 90 degrees. The angle is usually 45 degrees, unless another angle is specified. The fitting is usually indicated by the letter Y.

Alternative abbreviations conforming to the practice of the International Electrotechnical Commission.

Ampere	A	Kilovolt-ampere	kVA	Microfarad	μF	Milliampere	mA
Ampere-hour	Ah	Kilowatt	kW	Microwatt	μW	Volt	V
Coulomb	C			Milliampere	mA	Volt-ampere	VA
Farad	F	Kilowatthour	kWh	Millifarad	mF	Volt-coulomb	VC
Henry	H	Megawatt	MW	Millihenry	mH	Watt	W
Joule	J	Megohm	MΩ	Millivolt	mV	Watt-hour	Wh
Kilovolt	kV	Microampere	μA	Ohm	Ω	Volt	VA

Only the most commonly used terms have been included. These forms are recommended for those whose familiarity with the terms used makes possible a maximum of abbreviations. For others, less contracted combinations made up from this list may be used. For example, the list gives the abbreviation of the term "feet per second" as "fps." To some, however, ft per sec will be more easily understood.

Abbreviations should be used sparingly and only where their meaning will be clear. If there is any doubt, then spell out the term or unit of measurement.

The following points are good practice when preparing engineering documentation. Terms denoting units of measurement should be abbreviated in text only when preceded by the amounts indicated in numerals: "several inches," "one inch," "12 in." A sentence should not begin with a numeral followed by an abbreviation. The use of conventional signs for abbreviations in text should be avoided: use "lb," not "#" or "in," not ".

Symbols for the chemical elements are listed in the table on page 398.

Mathematical Signs and Commonly Used Abbreviations

+	Plus (sign of addition)	π	Pi (3.1416)
+	Positive	Σ	Sigma (sign of summation)
-	Minus (sign of subtraction)	ω	Omega (angles measured in radians)
-	Negative	g	Acceleration due to gravity (32.16 ft/s ² or 9.81 m/s ²)
\pm (\mp)	Plus or minus (minus or plus)	i (or j)	Imaginary quantity ($\sqrt{-1}$)
\times	Multiplied by (multiplication sign)	sin	Sine
\cdot	Multiplied by (multiplication sign)	cos	Cosine
\div	Divided by (division sign)	tan	Tangent
/	Divided by (division sign)	cot	Cotangent
:	Is to (in proportion)	sec	Secant
=	Equals	csc	Cosecant
\neq	Is not equal to	vers	Versed sine
\equiv	Is identical to	covers	Covered sine
\cong or \approx	Approximately equals	$\sin^{-1} a$	Arc the sine of which is a
>	Greater than	arcsin a or asin a	
<	Less than	$(\sin a)^{-1}$	Reciprocal of sin a ($1 \div \sin a$)
\geq	Greater than or equal to	$\sin^n x$	n th power of sin x
\leq	Less than or equal to	sinh x	Hyperbolic sine of x
\rightarrow	Approaches as a limit	cosh x	Hyperbolic cosine of x
\propto	Varies directly as	Δ	Delta (increment of)
\therefore	Therefore	δ	Delta (variation of)
$::$	Equals (in proportion)	d	Differential (in calculus)
$\sqrt{\quad}$	Square root	∂	Partial differentiation (in calculus)
$\sqrt[3]{\quad}$	Cube root	\int	Integral (in calculus)
$\sqrt[4]{\quad}$	4th root	\int_a^b	Integral between the limits a and b
$\sqrt[n]{\quad}$	n th root	!	$5! = 1 \times 2 \times 3 \times 4 \times 5$ (Factorial)
a^2	a squared (2nd power of a)	\sphericalangle	Angle
a^3	a cubed (3rd power of a)	\perp	Right angle
a^4	4th power of a	\perp	Perpendicular to
a^n	n th power of a	\triangle	Triangle
a^{-n}	$1 \div a^n$	\bigcirc	Circle
$\frac{1}{n}$	Reciprocal value of n	\square	Parallelogram
log	Logarithm	$^\circ$	Degree (circular arc or temperature)
\log_e	Natural or Napierian logarithm	'	Minutes or feet
ln	Natural or Napierian logarithm	"	Seconds or inches
e	Base of natural logarithms (2.71828)	a'	a prime
lim	Limit value (of an expression)	a''	a double prime
∞	Infinity	a_1	a sub one
α	Alpha	a_2	a sub two
β	Beta	a_n	a sub n
γ	Gamma	()	Parentheses
θ	Theta	[]	Brackets
ϕ	Phi	{ }	Braces
μ	Mu (coefficient of friction)	K	Absolute value of K , size of K irrespective of sign

commonly used to denote angles

Letter Symbols for Mechanics and Time-Related Phenomena

ANSI/ASME Y10.3M-1984

Acceleration, angular	α (alpha)	Height	h
Acceleration, due to gravity	g	Inertia, moment of	I or J
Acceleration, linear	a	Inertia, polar (area) moment of ^a	J

Energy, kinetic	E_k, K, T	Wavelength	λ (lambda)
Energy, potential	$E_p, V, \text{ or } \Phi$	Weight	W
Factor of safety ^a	$N, \text{ or } n$	Weight per unit volume	γ (gamma)
Force or load, concentrated	F	Work	W
Frequency	f		
Gyration, radius of ^a	k		

^a Not specified in Standard^b Specified in ANSI Y10.4-1982 (R1988)

MEASURING UNITS

Metric Systems Of Measurement

A metric system of measurement was first established in France in the years following the French Revolution, and various systems of metric units have been developed since that time. All metric unit systems are based, at least in part, on the International Metric Standards, which are the meter and kilogram, or decimal multiples or submultiples of these standards.

In 1795, a metric system called the centimeter-gram-second (cgs) system was proposed, and was adopted in France in 1799. In 1873, the British Association for the Advancement of Science recommended the use of the cgs system, and since then it has been widely used in all branches of science throughout the world. From the base units in the cgs system are derived the following:

Unit of velocity = 1 centimeter per second

Acceleration due to gravity (at Paris) = 981 centimeters per second per second

Unit of force = 1 dyne = $\frac{1}{981}$ gram

Unit of work = 1 erg = 1 dyne-centimeter

Unit of power = 1 watt = 10,000,000 ergs per second

Another metric system called the MKS (meter-kilogram-second) system of units was proposed by Professor G. Giorgi in 1902. In 1935, the International Electro-technical Commission (IEC) accepted his recommendation that this system of units of mechanics should be linked with the electromagnetic units by the adoption of a fourth base unit. In 1950, the IEC adopted the ampere, the unit of electric current, as the fourth unit, and the MKSA system thus came into being.

A gravitational system of metric units, known as the technical system, is based on the meter, the kilogram as a force, and the second. It has been widely used in engineering. Because the standard of force is defined as the weight of the mass of the standard kilogram, the fundamental unit of force varies due to the difference in gravitational pull at different locations around the earth. By international agreement, a standard value for acceleration due to gravity was chosen (9.81 meters per second squared) that for all practical measurements is approximately the same as the local value at the point of measurement.

The International System of Units (SI).—The Conference Generale des Poids et Mesures (CGPM), which is the body responsible for all international matters concerning the metric system, adopted in 1954, a rationalized and coherent system of units, based on the four MKSA units (see above), and including the *kelvin* as the unit of temperature and the *candela* as the unit of luminous intensity. In 1960, the CGPM formally named this system the *Système International d'Unites*, for which the abbreviation is SI in all languages. In 1971, the 14th CGPM adopted a seventh base unit, the *mole*, which is the unit of quantity ("amount of substance").

In the period since the first metric system was established in France toward the end of the 18th century, most of the countries of the world have adopted a metric system. At the present time, most of the industrially advanced metric-using countries are changing from their traditional metric system to SI. Those countries that are currently changing or considering change from the English system of measurement to metric have the advantage that they can convert directly to the modernized system. The United Kingdom, which can be said to have led the now worldwide move to change from the English system, went straight to SI.

The use of SI units instead of the traditional metric units has little effect on everyday life or trade. The units of linear measurement, mass, volume, and time remain the same, viz. meter, kilogram, liter, and second.

The SI, like the traditional metric system, is based on decimal arithmetic. For each physical quantity, units of different sizes are formed by multiplying or dividing a single base value by powers of 10. Thus, changes can be made very simply by adding zeros or shifting decimal points. For example, the meter is the basic unit of length; the kilometer is a multiple (1000 meters); and the millimeter is a sub-multiple (one-thousandth of a meter).

In the older metric systems, the simplicity of a series of units linked by powers of ten is an advantage for plain quantities such as length, but this simplicity is lost as soon as more complex units are encountered. For example, in different branches of science and engineering, energy may appear as the erg, the calorie, the kilogram-meter, the liter-atmosphere, or the horsepower-hour. In contrast, the SI provides only one basic unit for each physical quantity, and universality is thus achieved.

As mentioned before, there are seven base units, which are for the basic quantities of length, mass, time, electric current, thermodynamic temperature, amount of substance, and luminous intensity, expressed as the meter (m), the kilogram (kg), the second (s), the ampere (A), the kelvin (K), the mole (mol), and the candela (cd). The units are defined in the accompanying [Table 1](#).

The SI is a coherent system. A system is said to be coherent if the product or quotient of any two unit quantities in the system is the unit of the resultant quantity. For example, in a coherent system in which the foot is the unit of length, the square foot is the unit of area, whereas the acre is not.

Other physical quantities are derived from the base units. For example, the unit of velocity is the meter per second (m/s), which is a combination of the base units of length and time. The unit of acceleration is the meter per second squared (m/s^2). By applying Newton's second law of motion—force is proportional to mass multiplied by acceleration—the unit of force is obtained that is the kilogram-meter per second squared ($\text{kg}\cdot\text{m/s}^2$). This unit is known as the newton, or N. Work, or force times distance is the kilogram-meter squared per second squared ($\text{kg}\cdot\text{m}^2/\text{s}^2$), which is the joule (1 joule = 1 newton-meter), and energy is also expressed in these terms. The abbreviation for joule is J. Power or work per unit time is the kilogram-meter squared per second cubed ($\text{kg}\cdot\text{m}^2/\text{s}^3$), which is the watt (1 watt = 1 joule per second = 1 newton-meter per second). The abbreviation for watt is W. The term horsepower is not used in the SI and is replaced by the watt, which together with multiples and submultiples—kilowatt and milliwatt, for example—is the same unit as that used in electrical work.

The use of the newton as the unit of force is of particular interest to engineers. In practical work using the English or traditional metric systems of measurements, it is a common practice to apply weight units as force units. Thus, the unit of force in those systems is that force that when applied to unit mass produces an acceleration g rather than unit acceleration. The value of gravitational acceleration g varies around the earth, and thus the weight of a given mass also varies. In an effort to account for this minor error, the kilogram-force and pound-force were introduced, which are defined as the forces due to “standard gravity” acting on bodies of one kilogram or one pound mass, respectively. The standard gravitational acceleration is taken as 9.80665 meters per second squared or 32.174 feet per second squared. The newton is defined as “that force, which when applied to a body having a mass of one kilogram, gives it an acceleration of one meter per second squared.” It is independent of g . As a result, the factor g disappears from a wide range of formulas in dynamics. However, in some formulas in statics, where the weight of a body is important rather than its mass, g does appear where it was formerly absent (the weight of a mass of W kilograms is equal to a force of Wg newtons, where g = approximately 9.81 meters per second squared). Details concerning the use of SI units in mechanics calculations are given on [page 142](#) and throughout the Mechanics section in this Handbook. The use of SI units in strength of materials calculations is covered in the section on that subject.

Decimal multiples and sub-multiples of the SI units are formed by means of the prefixes given in the following table, which represent the numerical factors shown.

Factors and Prefixes for Forming Decimal Multiples of SI Units

Factor by which the unit is multiplied	Prefix	Symbol	Factor by which the unit is multiplied	Prefix	Symbol
10^{12}	tera	T	10^{-2}	centi	c
10^9	giga	G	10^{-3}	milli	m
10^6	mega	M	10^{-6}	micro	μ
10^3	kilo	k	10^{-9}	nano	n
10^2	hecto	h	10^{-12}	pico	p
10	deka	da	10^{-15}	femto	f
10^{-1}	deci	d	10^{-18}	atto	a

For more information on SI practice, the reader is referred to the following publications: *Metric Practice Guide*, published by the American Society for Testing and Materials, 1916 Race St., Philadelphia, PA 19103.

ISO International Standard 1000. This publication covers the rules for use of SI units, their multiples and sub-multiples. It can be obtained from the American National Standards Institute 11 West 42nd Street, New York, NY 10036.

The International System of Units, Special Publication 330 of the National Bureau of Standards—available from the Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402.

Binary Multiples.—The International Electrotechnical Commission has assigned the following prefixes to represent exponential binary multiples. This avoids confusion with standard SI decimal prefixes when representing powers of 2, as in bits and bytes.

Symbol	Name	Binary Power	Symbol	Name	Binary Power	Symbol	Name	Binary Power
Ki	kibi	2^{10}	Gi	gibi	2^{30}	Pi	pebi	2^{50}
Mi	mebi	2^{20}	Ti	tebi	2^{40}	Ei	exbi	2^{60}

Example 1: $2 \text{ Ki} = 2 \times 2^{10} = 2 \times 1,024 = 2,048$. This does *not* equal $2 \text{ K} = 2 \times 10^3 = 2,000$.

Example 2: $1 \text{ mebibyte} = 1 \times 2^{20} = 1,048,576$ bytes. Again this does *not* equal $1 \text{ megabyte} = 1 \times 10^6 = 1,000,000$ bytes, a value that is often confused with 1,048,576 bytes.

Table 1. International System (SI) Units

Physical Quantity	Name of Unit	Unit Symbol	Definition
Basic SI Units			
Length	meter	m	Distance traveled by light in vacuo during $1/299,792,458$ of a second.
Mass	kilogram	kg	Mass of the international prototype which is in the custody of the Bureau International des Poids et Mesures (BIPM) at Sèvres, near Paris.
Time	second	s	The duration of 9,192,631,770 periods of the radiation corresponding to the transition between the two hyperfine levels of the ground state of the cesium-133 atom.
Electric Current	ampere	A	The constant current which, if maintained in two parallel rectilinear conductors of infinite length, of negligible circular cross section, and placed at a distance of one meter apart in a vacuum, would produce between these conductors a force equal to 2×10^{-7} N/m length.
Thermodynamic Temperature	degree kelvin	K	The fraction $1/273.16$ of the thermodynamic temperature of the triple point of water.
Amount of Substance	mole	mol	The amount of substance of a system which contains as many elementary entities as there are atoms in 0.012 kilogram of carbon 12.
Luminous Intensity	candela	cd	Luminous intensity, in the perpendicular direction, of a surface of $1/600,000$ square meter of a black body at the temperature of freezing platinum under a pressure of 101,325 newtons per square meter.

Table 1. (Continued) International System (SI) Units

Physical Quantity	Name of Unit	Unit Symbol	Definition
SI Units Having Special Names			
Force	newton	$N = \text{kg}\cdot\text{m}/\text{s}^2$	That force which, when applied to a body having a mass of one kilogram, gives it an acceleration of one meter per second squared.
Work, Energy, Quantity of Heat	joule	$J = N\cdot\text{m}$	The work done when the point of application of a force of one newton is displaced through a distance of one meter in the direction of the force.
Electric Charge	coulomb	$C = A\cdot\text{s}$	The quantity of electricity transported in one second by a current of one ampere.
Electric Potential	volt	$V = W/A$	The difference of potential between two points of a conducting wire carrying a constant current of one ampere, when the power dissipated between these points is equal to one watt.
Electric Capacitance	farad	$F = C/V$	The capacitance of a capacitor between the plates of which there appears a difference of potential of one volt when it is charged by a quantity of electricity equal to one coulomb.
Electric Resistance	ohm	$\Omega = V/A$	The resistance between two points of a conductor when a constant difference of potential of one volt, applied between these two points, produces in this conductor a current of one ampere, this conductor not being the source of any electromotive force.
Magnetic Flux	weber	$\text{Wb} = V\cdot\text{s}$	The flux which, linking a circuit of one turn produces in it an electromotive force of one volt as it is reduced to zero at a uniform rate in one second.
Inductance	henry	$H = V\cdot\text{s}/A$	The inductance of a closed circuit in which an electromotive force of one volt is produced when the electric current in the circuit varies uniformly at the rate of one ampere per second.
Luminous Flux	lumen	$1\text{m} = \text{cd}\cdot\text{sr}$	The flux emitted within a unit solid angle of one steradian by a point source having a uniform intensity of one candela.
Illumination	lux	$1\text{x} = 1\text{m}/\text{m}^2$	An illumination of one lumen per square meter.

Table 2. International System (SI) Units with Complex Names

Physical Quantity	SI Unit	Unit Symbol
SI Units Having Complex Names		
Area	square meter	m^2
Volume	cubic meter	m^3
Frequency	hertz ^a	Hz
Density (Mass Density)	kilogram per cubic meter	kg/m^3
Velocity	meter per second	m/s
Angular Velocity	radian per second	rad/s
Acceleration	meter per second squared	m/s^2
Angular Acceleration	radian per second squared	rad/s^2
Pressure	pascal ^b	Pa
Surface Tension	newton per meter	N/m
Dynamic Viscosity	newton second per meter squared	$\text{N}\cdot\text{s}/\text{m}^2$
Kinematic Viscosity	} meter squared per second	m^2/s
Diffusion Coefficient		
Thermal Conductivity	watt per meter degree Kelvin	$\text{W}/(\text{m}\cdot^\circ\text{K})$
Electric Field Strength	volt per meter	V/m
Magnetic Flux Density	tesla ^c	T
Magnetic Field Strength	ampere per meter	A/m
Luminance	candela per square meter	cd/m^2

^a Hz = cycle/second^b Pa = newton/meter²^c T = weber/meter²

Standard of Length.—In 1866 the United States, by act of Congress, passed a law making legal the meter, the only measure of length that has been legalized by the United States Government. The United States yard is defined by the relation: 1 yard = $\frac{3600}{9937}$ meter. The legal equivalent of the meter for commercial purposes was fixed as 39.37 inches, by law, in July, 1866, and experience having shown that this value was exact within the error of observation, the United States Office of Standard Weights and Measures was, in 1893, authorized to derive the yard from the meter by the use of this relation. The United States prototype meters Nos. 27 and 21 were received from the International Bureau of Weights and Measures in 1889. Meter No. 27, sealed in its metal case, is preserved in a fireproof vault at the Bureau of Standards.

Comparisons made prior to 1893 indicated that the relation of the yard to the meter, fixed by the Act of 1866, was by chance the exact relation between the international meter and the British imperial yard, within the error of observation. A subsequent comparison made between the standards just mentioned indicates that the legal relation adopted by Congress is in error 0.0001 inch; but, in view of the fact that certain comparisons made by the English Standards Office between the imperial yard and its authentic copies show variations as great if not greater than this, it cannot be said with certainty that there is a difference between the imperial yard of Great Britain and the United States yard derived from the meter. The bronze yard No. 11, which was an exact copy of the British imperial yard both in form and material, had shown changes when compared with the imperial yard in 1876 and 1888, which could not reasonably be said to be entirely due to changes in Bronze No. 11. On the other hand, the new meters represented the most advanced ideas of standards, and it therefore seemed that greater stability as well as higher accuracy would be secured by accepting the international meter as a fundamental standard of length.

U.S. Customary Unit System

The USCS is originated from the foot-pound-second unit system or English unit system. The USCS system and English unit system are same for the measures of length and mass, but it varies for the measure of capacity. The U.S. gallon is defined as 231 cubic inches and bushel as 2,150.42 cubic inches where as the corresponding English units are 277.42 cubic inches and 2,219.36 cubic inches.

Fundamental Constants

Name	Symbol	USCS units	SI units
Avogadro's number	N_A		$6.022 \times 10^{23} \text{ mol}^{-1}$
Boltzman constant	k	$5.65 \times 10^{-24} \text{ ft}\cdot\text{lb}_f/\text{R}$	$1.38065 \times 10^{-23} \text{ J}/\text{K}$
Faraday Constant	F		96487 C/mol
Gravitational constant	g	$32.174 \text{ lb}_m\cdot\text{ft}/\text{lb}_f\cdot\text{sec}^2$	$9.80667 \text{ m}/\text{sec}^2$
Gravitational constant	G	$5.65 \times 10^{-24} \text{ ft}\cdot\text{lb}_f/\text{R}$	$6.672 \times 10^{-11} \text{ N}\cdot\text{m}^2/\text{kg}^2$
Specific gas constant	R	$53.3 \text{ ft}\cdot\text{lb}_f/\text{lb}_m\cdot\text{R}$	$287 \text{ J}/\text{kg}\cdot\text{K}$
Universal gas constant	R	$1545 \text{ ft}\cdot\text{lb}_f/\text{lbmol}\cdot\text{R}$	$8314 \text{ J}/\text{kmol}\cdot\text{K}$
Volume (molal ideal gas)	V	$359 \text{ ft}^3/\text{lbmol}$	$22.41 \text{ m}^3/\text{kmol}$
Pressure, atmospheric	P	$14.696 \text{ lb}_f/\text{in}^2$	$101330 \text{ Pa (n/m}^2)$
Temperature, standard	T	32°F	0°C
Density			
Air at 32°F (0°C)		$0.0805 \text{ lb}_m/\text{ft}^3$	$1.29 \text{ kg}/\text{m}^3$
Air at 70°F (20°C), 1 atm		$0.0749 \text{ lb}_m/\text{ft}^3$	$1.20 \text{ kg}/\text{m}^3$
Sea water		$64 \text{ lb}_m/\text{ft}^3$	$1025 \text{ kg}/\text{m}^3$
Fresh water		$62.4 \text{ lb}_m/\text{ft}^3$	$1000 \text{ kg}/\text{m}^3$
Mercury		$849 \text{ lb}_m/\text{ft}^3$	$13600 \text{ kg}/\text{m}^3$
Earth		$345 \text{ lb}_m/\text{ft}^3$	$5520 \text{ kg}/\text{m}^3$

20	240	241	242	243	244	245	246	247	248	249	250	251
30	360	361	362	363	364	365	366	367	368	369	370	371
40	480	481	482	483	484	485	486	487	488	489	490	491
50	600	601	602	603	604	605	606	607	608	609	610	611
60	720	721	722	723	724	725	726	727	728	729	730	731
70	840	841	842	843	844	845	846	847	848	849	850	851
80	960	961	962	963	964	965	966	967	968	969	970	971
90	1080	1081	1082	1083	1084	1085	1086	1087	1088	1089	1090	1091
100	1200	1201	1202	1203	1204	1205	1206	1207	1208	1209	1210	1211

Example: A tape measure reads 17 feet 8 inches. How many inches is this? *Solution:* Read down the first column of **Table 3** to find 10 ft 0 in = 120 inches. Next, find the intersection of the 7 ft row and the 8 inch column to get 92 inches. Add both results to get 120 inches + 92 inches = 212 inches.

Example: Convert $78\frac{3}{4}$ inches to feet. Solution: From Table 4, find 70 inches = 5.8333 feet and add to that $8\frac{3}{4}$ inches = 0.7292 feet found in Table 8a at the intersection of the $\frac{3}{4}$ inch row and the 8 inch column. Thus, $78\frac{3}{4}$ inches = 5.8333 + 0.7292 = 6.5625 feet.

All values in this table are exact. For inches to centimeters, shift decimal point in mm column one place to left and read centimeters, thus, for example, 40 in. = 1016 mm = 101.6 cm.

Table 8b. Millimeters to Inch Conversion

mm	inch	mm	inch	mm	inch	mm	inch	mm	inch	mm	inch
100	3.93701	10	0.39370	1	0.03937	0.1	0.00394	0.01	.000039	0.001	0.00004

500	152,400	50	15,240	5	1,524.0	0.5	152.40	0.05	15.240
600	182,880	60	18,288	6	1,828.8	0.6	182.88	0.06	18.288
700	213,360	70	21,336	7	2,133.6	0.7	213.36	0.07	21.336
800	243,840	80	24,384	8	2,438.4	0.8	243.84	0.08	24.384
900	274,320	90	27,432	9	2,743.2	0.9	274.32	0.09	27.432
1,000	304,800	100	30,480	10	3,048.0	1.0	304.80	0.10	30.480

Based on 1 inch = 25.4 millimeters, exactly. All values in this table are exact.

Example 1: Convert 293 feet, $5\frac{47}{64}$ inches to mm.

200 ft	=	60,960.0	mm
90 ft	=	27,432.0	mm
3 ft	=	914.4	mm
5	inch	=	127.0 mm
$\frac{47}{64}$	inch	=	18.653 mm
<hr/>			
293 ft $5\frac{47}{64}$	inch	=	89,452.053 mm

Example 2: Convert 71.86 feet to mm.

70.0	feet	=	21,336.0	mm
1.0	feet	=	304.8	mm
0.80	feet	=	243.84	mm
0.06	feet	=	18.288	mm
<hr/>				
71.86	feet	=	21,902.928	mm

Table 10. Mixed Fractional Inches to Millimeters Conversion for 0 to 41 Inches in $\frac{1}{64}$ -Inch Increments

Based on 1 inch = 25.4 millimeters, exactly. All values in this table are exact. Example: Convert $21\frac{23}{64}$ inches to millimeters. Solution: From the first page of this table, find 20 inches = 508.0 millimeters and add to that $1\frac{23}{64}$ inches = 34.528125 millimeters found at the intersection of the 1- inch column and the row containing $\frac{23}{64}$ inch. Thus, $21\frac{23}{64}$ inches = 508.0 + 34.528125 = 542.528125 mm, exactly.

1.000	25.4000

Based on 1 inch = 25.4 millimeters, exactly. All values in this table are exact. Use Table 8a to obtain whole inch and other decimal equivalents to add to decimal equivalents above. Example: Convert 10.9983 in. to mm. Solution: 10.9983 in. = 254.0 + 25.3492 + 0.00762 = 279.35682 mm.

490	12.446	12.4714	12.4968	12.5222	12.5476	12.573	12.5984	12.6238	12.6492	12.6746
500	12.7	12.7254	12.7508	12.7762	12.8016	12.827	12.8524	12.8778	12.9032	12.9286

Use the small table below to convert microinches to micrometers for ranges higher than given in the main table above. Appropriate quantities chosen from both tables are simply added to obtain the higher converted value:

µin.	µm	µin.	µm	µin.	µm	µin.	µm	µin.	µm
600	15.24	800	20.32	1000	25.4	1500	38.1	2100	53.34
700	17.78	900	22.86	1200	30.48	1800	45.72	2400	60.96

Both tables based on 1 microinch = 0.0254 micrometers, exactly. All values in both parts of this table are exact; figures to the right of the last place figures are all zeros.

Example: Convert 1375 µin. to µm:

$$\begin{array}{rcl}
 \text{From lower portion of Table 13a:} & 1200 \text{ } \mu\text{in.} & = & 30.48 \text{ } \mu\text{m} \\
 \text{From upper portion of Table 13a:} & 175 \text{ } \mu\text{in.} & = & 4.445 \text{ } \mu\text{m} \\
 & \underline{1375 \text{ } \mu\text{in.}} & = & \underline{34.925 \text{ } \mu\text{m}}
 \end{array}$$

4.60	181.1024	181.4961	181.8898	182.2835	182.6772	183.0709	183.4646	183.8583	184.2520	184.6457
4.70	185.0394	185.4331	185.8268	186.2205	186.6142	187.0079	187.4016	187.7953	188.1890	188.5827
4.80	188.9764	189.3701	189.7638	190.1575	190.5512	190.9449	191.3386	191.7323	192.1260	192.5197
4.90	192.9134	193.3071	193.7008	194.0945	194.4882	194.8819	195.2756	195.6693	196.0630	196.4567
5.00	196.8504	197.2441	197.6378	198.0315	198.4252	198.8189	199.2126	199.6063	200.0000	200.3937

The table given below can be used with the preceding main table to obtain higher converted values, simply by adding appropriate quantities chosen from each table:

µm	µin.	µm	µin.	µm	µin.	µm	µin.
10	393.7008	20	787.4016	30	1,181.1024	40	1,574.8032
15	590.5512	25	984.2520	35	1,378.9528	45	1,771.6535
						50	1,968.5039
						55	2,165.3543

Both portions of Table 13b are based on 1 microinch = 0.0254 micrometers, exactly.

Example: Convert 23.55 µm to µin.:

From above table: 20.00 µm = 787.4016 µin

From main table: 3.55 µm = 139.7638 µin

23.55 µm = 927.1654 µin

FEET TO METERS CONVERSION

<i>1 deciliter (dl) = 10</i> centiliters	
<i>1 centiliter (cl) = 10</i> milliliters	
	Shipping Measure
	For measuring internal capacity of a vessel:
	<i>1 register ton = 100</i> cubic feet
	For measurement of cargo:
	<i>1 shipping ton =</i>
	Approximately 40 cubic feet of merchandise is considered a shipping ton, unless that bulk would weigh more than 2000 pounds, in which case the freight charge may be based upon weight
	<i>40 cubic feet =</i>
	32.143 U.S. bushels
	31.16 Imperial bushels
	U.S. Liquid Measure
<i>1 British Imperial gallon =</i>	<i>1 U.S. gallon =</i>
0.1605 cubic foot	0.13368 cubic foot
277.42 cubic inches	231 cubic inches
1.2009 U.S. gallon	128 U.S. fluid ounces
160 Imperial fluid ounces	4 U.S. quarts
4 Imperial quarts	8 U.S. pints
8 Imperial pints	0.8327 British Imperial gallon
4,54609 liters	3,785411784 liters
<i>1 quart =</i>	<i>1 quart =</i>
2 Imperial pints	2 U.S. pints
8 Imperial gills	8 U.S. gills
40 Imperial fluid ounces	32 U.S. fluid ounces

Pitot Tube.— A pitot tube is a small, transparent, open tube bent at right angle. It is a hollow tube that is placed longitudinally in the direction of fluid flow, allowing the flow to enter one end at the fluids velocity of approach. When the fluids enter the pitot tube, it comes to a stop, all of the velocity head is converted to pressure head. The difference between the total and static energies is the kinetic energy of the fluid. The velocity of the fluid can be calculated by using the Bernoulli equation.

$$\frac{p_1}{\rho} + \frac{v_1^2}{2} = \frac{p_2}{\rho} \qquad v_1 = \sqrt{\frac{2(p_2 - p_1)}{\rho}} \text{ (SI)} \qquad v_1 = \sqrt{\frac{2(p_2 - p_1)g_c}{\rho}} \text{ (US)}$$

Units of Mass and Weight

Table 29. Mass and Weight Conversion Factors

Metric System	Avoirdupois or Commercial Weight
<i>1 metric ton (t) =</i>	<i>1 gross or long ton =</i>
1000 kilograms	2240 pounds
2204.6223 pounds	1.016 metric ton
0.9842 gross or long ton (of 2240 pounds)	1016 kilograms
0.9072 net or short ton (of 2000 pounds)	<i>1 net or short ton = 2000</i> pounds
<i>1 kilogram (kg) =</i>	<i>1 pound = 16</i> ounces
1000 grams = 10 hectograms	7000 grains
2.2046 pounds	0.45359237 kilogram
35.274 ounces avoirdupois	453.6 grams
<i>1 hectogram (hg) = 10</i> dekagrams	<i>1 ounce =</i>
<i>1 dekagram (dag) = 10</i> grams	$\frac{1}{16}$ pound
<i>1 gram (g) =</i>	16 drachms
10 decigrams	437.5 grains
0.0022046 pound	28.3495 grams
0.03215 ounce Troy	0.2780139 newton
0.03527 ounce avoirdupois	<i>1 grain Avoirdupois =</i>
15.432 grains	1 grain apothecaries' weight =
<i>1 decigram (dg) = 10</i> centigrams	1 grain Troy weight
<i>1 centigram (cg) = 10</i> milligrams	0.064799 gram

Troy Weight	Apothecaries' Weight
Used for Weighing Gold and Silver	<i>1 pound = 12</i> ounces = 5760 grains
<i>1 pound Troy =</i>	<i>1 ounce =</i>
12 ounces Troy = 5760 grains	8 drachms = 480 grains
$\frac{144}{175}$ Avoirdupois pound	31.103 grams
<i>1 ounce Troy =</i>	<i>1 drachm = 3</i> scruples = 60 grains
20 pennyweights = 480 grains	<i>1 scruple = 20</i> grains
31.103 grams	Old Weight Measures
<i>1 pennyweight = 24</i> grains	Measures for weight seldom used in the United States:
<i>1 grain Troy =</i>	<i>1 gross or long ton = 20</i> hundred-weights
1 grain avoirdupois	<i>1 hundred-weight = 4</i> quarters = 112 pounds
1 grain apothecaries' weight	<i>1 quarter = 28</i> pounds
0.0648 gram	<i>1 stone = 14</i> pounds
<i>1 carat (used in weighing diamonds) =</i>	<i>1 quintal = 100</i> pounds
3.086 grains	
200 milligrams = $\frac{1}{5}$ gram	
<i>1 gold karat = $\frac{1}{24}$</i> proportion pure gold	

Note: Figures in **Bold** indicate exact conversion values

1 newton meter = 8.850748 pound-inches

Poundal.—The expression “poundal” is sometimes used in connection with calculations in mechanics. Many mechanical handbooks, however, do not define it, because of its limited use. A poundal is a unit of force, and is defined as that force which, acting on a mass of one pound for one second, produces a velocity of one foot per second. A foot-poundal is a unit of energy equal to the energy resulting when a force of one poundal acts through a distance of one foot. In order to reduce foot-poundals to foot-pounds, multiply the number of foot-poundals by 0.03108. Dividing the number of foot-poundals by 32.16 (acceleration due to gravity) will also give foot-pounds.

Units of Energy, Power, and Heat

1 horsepower-hour =

- 0.746 kilowatt-hour
- 1,980,000 foot-pounds
- 2545 Btu (British thermal units)
- 2.64 pounds of water evaporated at 212°F
- 17 pounds of water raised from 62° to 212°F

1 kilowatt-hour =

- 100 watt-hours
- 1.34 horsepower-hour
- 2,655,200 foot-pounds
- 3,600,000 joules
- 3415 Btu
- 3.54 pounds of water evaporated at 212°F
- 22.8 pounds of water raised from 62° to 212°F

Table 43c. Power Conversion Factors

1 horsepower =

- 746 watts
- 0.746 kilowatt
- 33,000 foot-pounds/minute
- 550 foot-pounds/second
- 2545 Btu/hour
- 42.4 Btu/minute
- 0.71 Btu/second
- 2.64 pounds of water evaporated per hour at 212°F

1 kilowatt =

- 1000 watts
- 1.34 horsepower
- 2,654,200 foot-pounds/hour
- 44,200 foot-pounds/minute
- 737 foot-pounds/second
- 3415 Btu/hour
- 57 Btu/minute
- 0.95 Btu/second
- 3.54 pounds of water evaporated per hour at 212°F

1 watt =

- 1 joule/second
- 0.00134 horsepower
- 0.001 kilowatt
- 3.42 Btu/hour
- 44.22 foot-pounds/minute
- 0.74 foot-pounds/second
- 0.0035 pound of water evaporated per hour at 212°F

Table 43d. Heat Conversion Factors

1 Btu (British thermal unit) =

- 1052 watt-seconds
- 778 foot-pounds
- 0.252 kilogram-calorie
- 0.000292 kilowatt-hour
- 0.000393, horsepower-hour
- 0.00104 pound of water evaporated at 212°F

1 foot-pound =

- 1.36 joules
- 0.000000377 kilowatt-hour
- 0.00129 Btu
- 0.0000005 horsepower-hour
- 1 kilogram-meter =
- 7.233 foot-pounds

1 joule =

- 1 watt-second
- 0.00000078 kilowatt-hour
- 0.00095 Btu
- 0.74 foot-pound

1 kilogram calorie = 3.968 Btu

Conduction.—Whenever the molecules of a working substance, whether liquid, solid, or vapor, are restrained so that no appreciable relative translatory motion occurs among them, the kinetic energies of the various molecules will be largely due to vibration. If a temperature difference exists in the working substance, some adjacent molecules will necessarily be at different temperatures hence will possess different degrees of vibratory motion. In this case the molecule which is vibrating most rapidly will transfer some of its motion to the slower-moving molecule next to it, the one then undergoing a decrease in temperature and the other an increase. In this way, thermal energy will be transferred by the mechanism of conduction from the region of higher to the region of lower temperature. The process will continue spontaneously until the entire system has reached a uniform equilibrium temperature.

In contrast to radiation, conduction only occurs when a working substance is present and when the molecules of that working substance retain

practically fixed positions with respect to one another. Thus, conductive heat flow would always occur through solids, but would take place in liquids and vapors only if special conditions prevented or greatly reduced the normal translatory motion of the molecules within these materials.

Fuel Oil, Coal and Gas Equivalents.—One gallon of fuel oil equals 13.1 pounds of coal, equals 160 cubic feet of natural gas. One barrel of fuel oil equals 0.278 ton of coal, equals 680.6 cubic feet of natural gas. One pound of fuel oil equals 1.75 pounds of coal, equals 21.3 cubic feet of natural gas. One pound of coal equals 0.763 gallon of oil, equals 12.2 cubic feet of natural gas. One ton of coal equals 3.6 barrels of oil, equals 24,500 cubic feet of natural gas. The heating value of the average mid-continent fuel oil having a Baume gravity of 26.9 is 19,376 British thermal units per pound of oil, and 143,950 British thermal units per gallon of oil. The specific gravity and the heat value may be expressed approximately by means of a simple formula, as follows: BTU per pound = 18,650 + 40 × (Degrees Baume - 10).

Units of Temperature

Thermometer Scales.—There are two thermometer scales in general use: the Fahrenheit (F), which is used in the United States and in other countries still using the English system of units, and the Celsius (C) or Centigrade used throughout the rest of the world.

In the Fahrenheit thermometer, the freezing point of water is marked at 32 degrees on the scale and the boiling point, at atmospheric pressure, at 212 degrees. The distance between these two points is divided into 180 degrees. On the Celsius scale, the freezing point of water is at 0 degrees and the boiling point at 100 degrees. The following formulas may be used for converting temperatures given on any one of the scales to the other scale:

$$\text{Degrees Fahrenheit} = \frac{9 \times \text{degrees C}}{5} + 32$$

$$\text{Degrees Celsius} = \frac{5 \times (\text{degrees F} - 32)}{9}$$

Tables on the pages that follow can be used to convert degrees Celsius into degrees Fahrenheit or vice versa. In the event that the conversions are not covered in the tables, use those applicable portions of the formulas given above for converting.

Table 51. Temperature Conversion Formulas

To Convert	To	Use Formula	To Convert	To	Use Formula
Celsius, t_C	$^{\circ}\text{K}$, t_K	$t_K = t_C + 273.15$	Kelvin, t_K	$^{\circ}\text{C}$, t_C	$t_C = t_K - 273.15$
	$^{\circ}\text{F}$, t_F	$t_F = 1.8 t_C + 32$		$^{\circ}\text{F}$, t_F	$t_F = 1.8 t_K - 459.67$
	$^{\circ}\text{R}$, t_R	$t_R = 9(t_C + 273.15)/5$		$^{\circ}\text{R}$, t_R	$t_R = 9/5 \times t_K$
Fahrenheit, t_F	$^{\circ}\text{K}$, t_K	$t_K = (t_F + 459.67)/1.8$	Rankine, t_R	$^{\circ}\text{K}$, t_K	$t_K = 5/9 \times t_R$
	$^{\circ}\text{C}$, t_C	$t_C = (t_F - 32)/1.8$		$^{\circ}\text{C}$, t_C	$t_C = 5/9 \times t_R - 273.15$
	$^{\circ}\text{R}$, t_R	$t_K = t_F - 459.67$		$^{\circ}\text{F}$, t_F	$t_F = t_R - 459.67$

Absolute Temperature and Absolute Zero.—A point has been determined on the thermometer scale, by theoretical considerations, that is called the absolute zero and beyond which a further decrease in temperature is inconceivable. This point is located at -273.15 degrees Celsius or -459.67 degrees F. A temperature reckoned from this point, instead of from the zero on the ordinary thermometers, is called absolute temperature. Absolute temperature in degrees C is known as “degrees Kelvin” or the “Kelvin scale” (K) and absolute temperature in degrees F is known as “degrees Rankine” or the “Rankine scale” (R).

$$\text{Degrees Kelvin} = \text{degrees C} + 273.15$$

$$\text{Degrees Rankine} = \text{degrees F} + 459.67$$

Measures of the Quantity of Thermal Energy.—The unit of quantity of thermal energy used in the United States is the British thermal unit, which is the quantity of heat or thermal energy required to raise the temperature of one pound of pure water one degree F. (American National Standard abbreviation, Btu; conventional British symbol, B.Th.U.) The French thermal unit, or *kilogram calorie*, is the quantity of heat or thermal energy required to raise the temperature of one kilogram of pure water one degree C. One kilogram calorie = 3.968 British thermal units = 1000 gram calories. The number of foot-pounds of mechanical energy equivalent to one British thermal unit is called the *mechanical equivalent of heat*, and equals 778 foot-pounds.

In the modern metric or SI system of units, the unit for thermal energy is the *joule* (J); a commonly used multiple being the kilojoule (kJ), or 1000 joules. See page 2544 for an explanation of the SI System. One kilojoule = 0.9478 Btu. Also in the SI System, the *watt* (W), equal to joule per second (J/s), is used for power, where one watt = 3.412 Btu per hour.

Table converts °C → °F and °R, or °F → °C and °K. Find "convert from" temperature in **bold** column and read result from °F and °R or °C and °K columns. Example 1: 183 °C = 361.4 °F and 821.1 °R. Example 2: 183 °F = 83.9 °C and 357.0 °K.

Units of Velocity and Acceleration

Table 53. Velocity Conversion Factors

To Convert ↓	Multiply By Factor, To Obtain ↓	cm/sec	m/sec	km/hr	ft/sec	ft/min	ft/hr	knot ^a	mile/hr
cm/sec		1	0.01	0.036	0.032808	1.9685	118.110236	0.01944	0.02237

Figures in **bold face** indicate the conversion is exact.

Units of Viscosity

Table 55a. Oil Viscosity Conversion Factors

To Convert ↓	Multiply By This Factor, To Obtain ↓	Poise (P)	Centi-poise (Z)	Reyn (μ)	Stoke (S)	Centistoke (v)
Poise (P)		$\frac{\text{dyne-s}}{\text{cm}^2} = \frac{\text{gram mass}}{\text{cm-s}}$	1	100	1.45×10^{-5}	$\frac{1}{\rho}$
Centipoise (Z)	$\frac{\text{dyne-s}}{100 \text{ cm}^2} = \frac{\text{gram mass}}{100 \text{ cm-s}}$	0.01	1	1.45×10^{-7}	$\frac{0.01}{\rho}$	$\frac{1}{\rho}$
Reyn (μ)	$\frac{\text{lb force-s}}{\text{in}^2}$	6.9×10^4	6.9×10^6	1	$\frac{6.9 \times 10^4}{\rho}$	$\frac{6.9 \times 10^6}{\rho}$
Stoke (S)	$\frac{\text{cm}^2}{\text{s}}$	ρ	100 ρ	$1.45 \times 10^{-5} \rho$	1	100
Centistoke (v)	$\frac{\text{cm}^2}{100 \text{ s}}$	0.01 ρ	ρ	$1.45 \times 10^{-7} \rho$	0.01	1

Table 55b. Additional Viscosity Conversion Factors

Multiply	By	To Obtain	Multiply	By	To Obtain
centipoise	0.001	pascal-second (Pa · s)	pascal-second	1000	centipoise
centistoke	0.000001	meter ² /second (m ² /s)	pascal-second	10	poise
stoke	0.0001	meter ² /second (m ² /s)	poise	0.1	pascal-second (Pa-s)

ρ = Specific gravity of the oil.

Figures in **bold face** indicate the conversion is exact

Units of Moment of Inertia and Momentum

Table 56. Moment of Inertia Conversion Factors

Multiply	By	To Obtain
Moment of Inertia and Section Modulus		
moment of inertia [kg · m ²]	23.73036	pound-foot ²
moment of inertia [kg · m ²]	3417.171	pound-inch ²
moment of inertia [lb · ft ²]	0.04214011	kilogram-meter ² (kg · m ²)
moment of inertia [lb · inch ²]	0.0002926397	kilogram-meter ² (kg · m ²)
moment of section [foot ⁴]	0.008630975	meter ⁴ (m ⁴)
moment of section [inch ⁴]	41.62314	centimeter ⁴
moment of section [meter ⁴]	115.8618	foot ⁴
moment of section [centimeter ⁴]	0.02402510	inch ⁴
section modulus [foot ³]	0.02831685	meter ³ (m ³)
section modulus [inch ³]	0.00001638706	meter ³ (m ³)
section modulus [meter ³]	35.31466	foot ³
section modulus [meter ³]	61,023.76	inch ³

Table 57. Momentum Conversion Factors

Multiply	By	To Obtain
Momentum		
kilogram-meter/second	7.233011	pound-foot/second
kilogram-meter/second	86.79614	pound-inch/second
pound-foot/second	0.1382550	kilogram-meter/second (kg · m/s)
pound-inch/second	0.01152125	kilogram-meter/second (kg · m/s)

Miscellaneous Measuring Units

- 1 great gross* = 12 gross = 144 dozen
- 1 gross* = 12 dozen = 144 units
- 1 dozen* = 12 units
- 1 quire* = 24 sheets
- 1 ream* = 20 quires = 480 sheets
- 1 ream printing paper* = 500 sheets
- 1 score* = 20 units

Ohm's Law.—The following figure represents basic electrical relationships. This chart has been formatted in such a way that each variable has been related to the other three variables. This figure is simply for reference.

Key to variables:
 V = Voltage (Volts)
 R = Resistance (Ohms)
 I = Current (Amps)
 W = Power (Watts)

Circular Model of Electrical Relations

5052 403, 579, 581		for polishing plastics 625	

INDEX OF MATERIALS

2712

Aluminum silicate
density 415
mechanical properties 415

Al₂O₃ (Alumina)
density 415
mechanical properties 415

Americium
element properties 398

Ammonia
boiling point 399
latent heat of evaporation 399
specific gravity 408
specific heat 400

Ammonium nitrate (NH₄NO₃)
in freezing mixtures 403

Amosite
thermal conductivity and
conductance 401

AMS 2404C 1467

AMS 2405B 1467

AMS 2433B 1467

Aniline
boiling point 399

Antimony
coefficient of heat transmission 402
element properties 398
specific heat 400

Argon
element properties 398

Arsenic
element properties 398

Asbestos
specific gravity 407

Asbestos cement
thermal conductivity and
conductance 401

Asbestos paper
thermal conductivity and
conductance 401

Ash
machinability of 414
weight of 413

Aspen
machinability of 414
weight of 413

Asphalt roll
thermal conductivity and
conductance 401

Asphaltum
specific gravity 407

Astatine
element properties 398

Atomic number and weight 398

Atomic symbol, elements 398

Azdel
density 416
mechanical properties 416
specific gravity 416

B

Barium
element properties 398

Basswood
machinability of 414
mechanical properties 412
weight of 413

Beech
machinability of 414
weight of 413
weight per cord 412

Beeswax
latent heat of fusion 399

Bending modulus 601

Bending strength 601

Bending stress
safe
various plastics 627

Benzine
boiling point 399
specific gravity 408
specific heat 400

Berkelium
element properties 398

Beryllium
element properties 398

Birch
machinability of 414
weight of 413

Bismuth
element properties 398
latent heat of fusion 399

Bisulfide of carbon
ignition temperature 403

Block
thermal conductivity and conductance
cinder 401
concrete 401

Board foot
weight of wood per 412

Boiling points
various substances 399

Borax 543
specific gravity 407

Boric acid 543

Boron
element properties 398

Brass
coefficient of expansion 402
red
coefficient of heat transmission 402
specific heat 400
yellow
coefficient of heat transmission 402

Brick
coefficient of expansion 402
specific gravity 407
thermal conductivity and conductance

2917 Browning Iron and Steel	2930 Power for Operating Steam Hammers
2917 To Produce a Bronze Color	2931 Board Drop-hammers
2917 To Produce a Gray Color	2932 Forging Presses
2917 Mottled Coloring	2933 Air Pressures and Pipe Sizes for Forges
2917 Coppering Solution	2933 The Cold Swaging Process
2917 White Coatings for Laying Out Lines	2934 Forging Machines
2917 To Produce Gray Colors	2934 Dies for Bolt and Rivet Forging Machines
2918 Blue and Violet Shades	2934 Dies and Tools Used in Hot-pressed Center-feed Nut Machines
2918 To Give Brass a Green Tint	2934 Bulldozer Dies
2918 Etching And Etching Fluids	2934 Helve Hammers
2918 Etching Fluids for Different Metals	2934 Vertical Power Hammers
2919 Etching Brass Nameplates	2934 Efficiency of Forging Hammers
2919 Producing a Black Background	2936 Machinery and Hammer Foundations
2919 Etching Ornamental Designs in Metal	2936 Concrete Foundations
MANUFACTURING	2937 Drop Hammer Foundations
2921 Welding with Thermit	2937 Foundation for Steam Hammer
2921 Thermit Process	2937 Machine and Forge Shop Floor Materials
2921 Preparation of Part to be Welded	2938 Concrete and Wooden Floors
2921 Mold for Thermit Welding	2938 To Prevent Dust on Concrete Floors
2922 Thermit Required for Welding	2938 Floors for Forge Shops
2922 Thermit Additions	2939 Drop-Forging Dies
2922 Pre-heating — Making a Weld	2939 Steel for Drop-forging Dies
2923 Filling Shrinkage Holes and Surface Flaws	2939 Allowance for Shrinkage
2923 Composition of Thermit Steel	2939 Draft Allowance
2923 High- and Low-pressure Torches	2939 Locating Impression in the Die
SYMBOLS FOR DRAFTING	2939 Obtaining Weight of Forging from Lead Proof
2924 Symbols For Drafting	2940 Amount of Flash for Drop-forging Dies
2924 Air Conditioning Symbols	2940 The Break-down of Drop-forging Dies
2925 Heating and Ventilation Symbols	2940 Hardening Drop-forging Dies
2926 Valve Symbols	2940 Heating the Die
2927 Piping Symbols	2940 Cooling the Heated Die
2928 Pipe Fittings Symbols	2941 Tempering Dies

TABLE OF CONTENTS
ADDITIONAL ONLY ON THE CD

FORGE SHOP EQUIPMENT	
<i>(Continued)</i>	
2941	Dies for Bronze and Copper Forgings
2941	Trimming Dies for Drop-forgings
2941	Standard Tolerances for Forgings
2944	Welding Methods
2944	Classes of Welds
2944	Welding Heat
2944	Fire for Welding
2944	Fluxes for Welding
2945	Fuels for Forge
2945	Machine Welding
2946	Hydraulic Press
2946	Rules and Formulas for Hydraulic Press Calculations

SILENT OR INVERTED TOOTH CHAIN

2948	Characteristics of Silent Chain Drives
2948	Standard Silent Chain Designation
2949	Silent Chain Links
2949	Silent Chain Sprocket Diameters
2949	Silent Chain Sprocket Profiles and Chain Widths
2959	Sprocket Hub Dimensions
2963	Sprocket Design and Tooth Form
2963	Cutting Silent Chain Sprocket Teeth
2965	Design of Silent Chain Drives
2965	Pitch of Silent Chain
2965	Maximum Ratios for Silent Chain Drives
2966	Center Distance for Silent Chain Drives
2966	Silent Tooth Chain Horsepower Capacity
2966	Installation of Silent Chain Drives
2967	Double-Flexure Silent Chain
2967	Horsepower Ratings Per Inch of Chain Width for Silent Chain Drives — 1982

GEARS AND GEARING

2971	Geometry Factors For Gear Teeth
2971	Contact and Bending Stresses
2971	Geometry Factors for Pitting Resistance and Bending Strength

GEARS AND GEARING	
<i>(Continued)</i>	
2971	Exceptions to the Information Sheet Data and Procedures
2971	Basic Gear Geometry of Spur and Helical Gears
2973	Contact Ratios
2974	Minimum Lengths of Lines of Contact
2974	Load Sharing Ratio, mN
2974	Calculating the Pitting Resistance Geometry Factor, I
2975	Bending Strength Geometry Factor, J
2976	Pressure Angle at Load Application Point
2977	Generating-Rack Shift Coefficient
2978	Tables of Geometry Factors, I and J
2978	Using the Tables
2987	Power-Transmitting Capacity of Spur Gears
2987	Modes of Failure
2987	Strength Calculations for Spur and Helical Gears
2988	Rating Formulas
2988	Exceptions
2988	Additional Considerations
2989	Criteria for Gear Tooth Capacity
2989	Relationship of Pitting Resistance and Bending Strength Ratings
2990	Fundamental Rating Formulas
2990	Pitting Resistance
2991	Symbols Used in Gear Rating Equations
2993	Pitting Resistance Power Rating
2993	Contact Load Factor, K
2994	Bending Strength
2994	Allowable Bending Stress Number
2994	Bending Strength Power Rating
2995	Values for Factors Applied in Fundamental Equations
2995	Rim Thickness Factor KB
2995	Geometry Factors I and J
2995	Transmitted Tangential Load, Wt
2996	Dynamic Factors, Cv and Kd
2998	Application Factors, Ca and Ka
2998	Service Factors, CSF and KSF
2999	Elastic Coefficient, Cp
2999	Surface Condition Factor, Cf

GEARS AND GEARING	MISCELLANEOUS TOPICS
<i>(Continued)</i>	
2999 Size Factors, Cs and Ks	3033 Mathematics
2999 Load Distribution Factors, Cm and Km	3033 Catenary Curve
3001 Allowable Stress Numbers, Sac and Sat	3033 Mechanics
3002 Case Depth of Surface-Hardened Gears	3033 Running Balance
3003 Momentary Overloads	3033 Properties of Materials
3003 Yield Strength	3033 Copper-Clad Steel
3003 Hardness Ratio Factor CH	3033 Truflex
3004 Life Factors CL and KL	3033 Firebrick Properties
3005 Localized Yielding	3033 Inconel
3005 Reliability Factors, CR and KR	3034 Inconel "X"
3005 Temperature Factors CT and KT	3034 Lodestone
3007 Worm Gearing	3034 Metallography
3007 Standard Design for Fine-pitch	3035 Micarta
3008 Formulas for Proportions of Wormgears	3035 Monel
3009 Proportions of Fine-pitch Worms and Wormgears	3036 "R" Monel
3017 Materials for Worm Gearing	3036 "K" Monel
3017 Single-thread Worms	3036 "KR" Monel
3017 Multi-thread Worms	3036 "S" Monel
3019 Ratio for Obtaining "Hunting Tooth" Action	3036 "H" Monel
3020 Pitch Diameter of Worm	3036 Nichrome
3020 Addendum and Dedendum	3037 Nickel Alloy for Resisting Acids
3021 Outside Diameter of Wormgear	3037 Duronze
3021 Pressure Angles	3038 Aluminum Alloys, Wrought, Sheet
3021 Designing Worm Gearing Relative to Center Distance and Ratio	3038 Plow-steel Wire Rope
3022 Efficiency of Worm Gearing	3038 Type Metal
3026 Self-locking or Irreversible Worm Gearing	3038 Vanadium Steel
3027 Worm Gearing Operating Temperatures	3038 Wood's Metal
3027 Thermal Rating	3039 Lumber
3027 Water and Forced-Air Cooling	3039 Lumber, Manufactured
3027 Double-enveloping Worm Gearing	3039 Lumber Water Content
3029 Worm Thread Cutting	3040 Dimensioning, Gaging, and Measuring
3029 Wormgear Hobs	3040 Transfer Calipers
3030 Helical Fluted Hobs	3040 Wheatstone Bridge
3032 Gear Shaving	3041 Tools and Tooling
	3041 Rotary Files and Burs
	3041 Tooth-rest for Cutter Grinding
	3042 Machining Operations
	3042 Feed Rate on Machine Tools
	3042 Billet
	3042 Milling Machines, Lincoln Type
	3042 Saddle
	3043 Cold Extrusion
	3043 Transfer Machines

To find the square of a given whole number, divide the number by 10 and find the row in the first column that contains the whole number portion of the result. The selected row contains the square of given number under the column corresponding to the last digit in the number.

Example: The square of 673, found in row labeled 67, under column labeled 3, is given as 452,929.

Squares of Mixed Numbers from $\frac{1}{64}$ to 6, by 64ths

CEMENT, CONCRETE, LUTES, ADHESIVES, AND SEALANTS**Cement**

The cements used in concrete construction are classified as:

- 1) Portland cements.
- 2) Natural cements.
- 3) Pozzuolanic, pozzuolan, or slag cements.

These different classes are all hydraulic cements as they will set or harden under water. When the powdered cement is mixed with water to a plastic condition, the cement sets or solidifies as the result of chemical action. After the preliminary hardening or initial set, the cement slowly increases in strength, the increase extending over months or years.

Portland Cement.— Portland and natural cements are the kinds most commonly used. Portland cement should be used for all structures which must withstand stresses and for masonry that is either under water or heavily exposed to water or the weather. According to the specifications of the American Society for Testing Materials, the specific gravity of Portland cement must be not less than 8:1. If the tested cement is below this requirement. A second test should be made on a sample ignited at a low red heat. The ignited cement should not lose more than four per cent of its weight. A satisfactory Portland cement must not develop initial set in less than 30 minutes; it must not develop hard set in less than 1 hour; but the time required for developing hard set must not exceed 10 hours. The minimum requirements for tensile strength in pounds, for briquettes one square inch in cross-section, should be as follows:

For cement 24 hours old in moist air, 175 pounds.

For cement 7 days old, one day in moist air and six days in water, 500 pounds.

For cement 28 days old, one day in moist air and 27 days in water, 600 pounds.

For one part of cement and three parts of standard Ottawa sand, 7 days old, one day in moist air and six days in water, 200 pounds.

For one part of cement and three parts of standard Ottawa sand, 28 days old, one day in moist air and 27 days in water, 275 pounds.

The cements must under no circumstances show a decrease in strength during the time periods specified.

Natural Cement.— Natural cement is used in mortar for ordinary brick work and stone masonry, street sub-pavements, as a backing or filling for massive concrete or stone masonry, and for similar purposes. Natural cement does not develop its strength as quickly and is not as uniform in composition as Portland cement. It should not be used for columns, beams, floors or any structural members which must withstand considerable stress. Natural cement is also unsuitable for work that is exposed to water. Foundations which are subjected to moderate compressive stresses may be made of natural cement, which is also satisfactory for massive masonry where weight rather than strength is the essential feature.

The American Society for Testing Materials gives the following specifications for natural cement: An initial set must not develop in less than 10 minutes, and the hard set must not develop in less than 30 minutes, but must develop in less than three hours. The minimum requirements for tensile strength in pounds, for briquettes one inch in cross-section, are as follows:

For natural cement 24 hours old in moist air, 75 pounds.

For natural cement 7 days old, one day in moist air and six days in water, 150 pounds.

For natural cement 28 days old, one day in moist air and 27 days in water, 250 pounds.

For one part of cement and three parts of standard Ottawa sand, 7 days old, one day in moist air and six days in water, 50 pounds.

For one part of cement and three parts of standard Ottawa sand, 28 days old, one day in moist air and 27 days in water, 125 pounds.

Pozzolan or Slag Cement.—This cement is adapted for structures which are constantly exposed to fresh or salt water and for drains, sewers, foundation work underground, etc. It is not suitable where masonry is exposed to dry air for long periods. Pozzolan cement sets slowly but its strength increases considerably with age. While this cement is relatively cheap, it is not as strong, uniform, or reliable as Portland and natural cements, and is not used extensively.

Concrete

Concrete.—The principal ingredients of concrete are the matrix or mortar and the “coarse aggregate.” The matrix consists of cement and sand mixed with water, and the coarse aggregate is usually broken stone or gravel. What is known as *rubble concrete* or cyclopean masonry contains large stones which are used for reducing the cost of massive dams and walls. These rubble stones may vary from a few per cent to over one-half the volume. When concrete without much strength but light in weight is required, cinders may be used. This cinder concrete is porous and is used for light floor construction or fire-proofing.

Concrete Mixtures.—In the mixing of concrete, it is desirable to use as little cement as is consistent with the required strength, because the cement is much more expensive than the other ingredients. The proportioning of the ingredients is usually by volume and mixtures are generally designated by giving the amount of each ingredient in a fixed order, as 1 : 2 : 5, the first figure indicating the amount of cement by volume, the second the amount of sand, and the third the amount of broken stone or gravel.

For ordinary machine foundations, retaining walls, bridge abutments, and piers exposed to the air, a 1 : 2½ : 5 concrete is satisfactory; and for ordinary foundations, heavy walls, etc., a lean mixture of 1 : 3 : 6 may be used. For reinforced floors, beams, columns, and arches, as well as for machine foundations which are subjected to vibration, a 1 : 2 : 4 concrete is generally used. This composition is also employed when concrete is used under water. For water tanks and similar structures subjected to considerable pressure and required to be water-tight, mixtures rich in cement and composed of either 1 : 1 : 2 or 1 : 1½ : 3 concrete are used. Portland cement should preferably be used in concrete construction.

Sand, Gravel, and Stone for Concrete.—The sand used must be free from dust, loam, vegetable, or other organic matter; it should pass, when dry, through a screen with holes of ¼-inch mesh. The gravel should consist of clean pebbles free from foreign matter and should be of such coarseness that it will not pass through a screen of ¼-inch mesh. Gravel containing loam or clay should be washed by a hose before mixing. The broken stone should be of a hard and durable kind, such as granite or limestone. This stone should pass through a 2½-inch screen.

Amount of Water for Mixing Concrete.—The amount of water required to combine chemically with cement is about 16 per cent by weight, but in mixing concrete a greater amount than this must be used, because of losses and the difficulty of uniformly distributing the water. In hot weather more water is required than in cool weather because of the loss due to evaporation. The same applies when absorbent sand is used, or when the concrete is not rammed tightly. An excess of water is not desirable, because this excess will flow away and carry some of the cement with it. The water must be free from oils, acids, and impurities that would prevent a proper chemical combination with the cement. It is important to mix the ingredients thoroughly. Lime cement, sand and stone should be mixed while dry, preferably using a machine. Enough water should then be added to produce a mixture which will flow readily and fill different parts of the form.

Reinforced Concrete.—Concrete reinforced with steel is widely used, especially where the concrete must resist tensile as well as compressive stresses. This reinforcement may be in the form of round bars twisted square bars, corrugated bars, expanded metal, steel mesh, or wire fabric. The proportions for reinforced concrete structures are usually 1 : 2 : 4, or 1

barrel of portland cement, 2 barrels of sand, and 4 barrels of broken stone or gravel. The lateral spacing between reinforcement bars should not be less than three times the bar diameter from center to center, with a clear space between the bars of at least one inch. The distance from the side of a beam to the center of the nearest bar should be not less than two diameters.

Strength of Concrete.—The strength varies greatly depending upon the quality and proportions of the ingredients and the care in mixing and depositing in the forms. The compressive strength of concrete which, after having been mixed and laid, has set 28 days, varies from 1000 to 3300 pounds per square inch, according to the mixture used. If made in the proportion 1 : 3 : 6, using soft limestone and sandstone a compressive strength of only 1000 pounds per square inch may be expected, whereas a mixture of 1 : 1 : 2, made with soft limestone and sandstone, will show a strength of 2200 pounds per square inch. A mixture of 1 : 3 : 6, made from granite or trap rock, will have a compressive strength of 1400 pounds per square inch, while a mixture of 1 : 1 : 2, made from granite or trap rock, will have a strength of 3300 pounds per square inch. Other mixtures will have values between those given. The richer in cement in proportion to sand, gravel, and stone, the stronger will be the concrete. The strongest concretes are also obtained by using granite or trap rock. A medium strength is obtained by using gravel, hard limestone, or hard sandstone, whereas the least strength is obtained by using soft limestone or sandstone. Concrete may also be mixed with cinders, but, in this case, very inferior strength is obtained; the richest mixtures will only give a strength of about 800 pounds per square inch.

Durability of Concrete in Sea Water.—Experiments have been made to determine the durability of different mixtures of concrete when exposed to sea water. It has been found that the mixtures that give the best results are those that are richest in cement. Mixtures of 1 : 1 : 2, for example, will give much better results than mixtures of 1 : 3 : 6. Also, very wet mixtures seem to give better results than those that are comparatively dry when deposited. It has also been found that, in order to insure the permanence of Portland cement concrete in sea water, the cement must contain as little lime and alumina as possible and must also be free from sulfates, and the proportion of sand and stones in the concrete must be such that the structure is practically non-porous. Natural cement should never be used for concrete exposed to sea water.

Waterproofing Concrete.—Several formulas for making concrete waterproof have been successfully used but some of them are too expensive for general application. One of the simplest, cheapest, and most effective is that developed by the U.S. Geological Survey. A heavy residual mineral oil of 0.93 specific gravity, mixed with Portland cement, makes it waterproof and does not weaken when the concrete consists of, say, cement, 1 part, sand, 3 parts, and oil, not more than 10 per cent, by weight, of the cement. Concrete mixed with oil requires about fifty per cent longer time to set hard, and the compressive strength is slightly decreased but not seriously. The bond or grip of oil concrete on steel is much decreased when plain bars are used, but formed bars, wire mesh, or expanded metal act as effectively in it as in ordinary concrete.

Resistance to Acids and Oils.—Concrete of a good quality, that has thoroughly hardened, resists the action of acids and mineral oils as well as other building materials, but vegetable oils containing fatty acids produce injurious effects by combining with the lime in the cement and causing disintegration of the concrete.

Lutes and Cements

Luting and cementing materials for various purposes in the laboratory and shops may be classified as follows: water- and steam-proof; oil-proof; acid-proof; proof to hydrocarbon gases; chlorine-proof; elastic; general purposes; marine glue; gaskets; machinists; leather (belting); crucible; iron; and stone.

Water-proof Compositions.—The asphalt fluid coatings for reservoir wall, concrete foundations, brick, wood, etc., are often of use to engineers. Asphalt only partly dissolves in petroleum naphtha, but when heated in a steam-jacketed kettle and not thinned out too much, a mixture of the two may be obtained in which the part of the asphalt not dissolved is held in suspension. Asphalt is entirely soluble in benzol or toluol, which are about the cheapest solvents for all the constituents of asphalt. Tar and pitch are sometimes used in this connection, but tar contains water, light oils and free carbon, and does not wear as well as good refined asphalt; pitch also contains free carbon, which is sometimes objectionable when it is thinned out with a solvent. Asphalt alone is somewhat pervious to water, but it can be improved in this respect by adding about one-fourth its weight of paraffin; it is also well to add a little boiled linseed oil. For thicker compositions, where body is required, asbestos, stone powder, cement, etc., may be added as fillers. Lutes of linseed oil thickened with clay, asbestos, red or white lead, etc., are waterproof if made thick enough. These are much used for steam joints. Flaxseed meal made into a paste with water is often serviceable, the oil contained serving as a binder as the water evaporates.

Oil-proof Cements.—The well-known “hektograph composition” is the most useful lute for small leaks, etc. It consists of the following ingredients: Good glue or gelatin, 2 parts; glycerin, 1 part; water, 7 parts. This preparation is applied warm and stiffens quickly on cooling. Another very useful composition is a stiff paste of molasses and flour. Another preparation, impervious to oil vapors, is the “flaxseed poultice,” mentioned in the preceding paragraph, which is proof to oil vapors. One of the strongest cements, and one which is really oil-proof, waterproof and acid-proof, is a stiff paste of glycerin and litharge. These form a chemical combination which sets in a few minutes. If a little water is added, it sets more slowly, which is often an advantage. This cement is mixed when required for use. A mixture of plaster-of-paris and water is useful, and it is sometimes advantageous to mix straw or hair with it. A solution of silicate of soda made into a stiff paste with carbonate of lime gets hard in six to eight hours.

Acid-proof Cements.—The asphalt compositions already mentioned, compositions of melted sulphur with fillers of stone powder, cement, sand, etc., may be used, and also the following, which withstands hydrochloric acid vapors: rosin, 1 part; sulphur, 1 part; fireclay, 2 parts. The lute composed of boiled linseed oil and fireclay acts well with most acid vapors. The composition of glycerin and litharge previously referred to is useful in this connection, especially when made up according to the following formula: Litharge, 80 pounds; red lead, 8 pounds; “flock” asbestos, 10 pounds. It should be fed into a mixer, a little at a time, with small quantities of boiled oil (about six quarts of oil being used). Sockets in 3-inch pipes carrying nitric acid, calked with this preparation, showed no leaks in nine months.

A particularly useful cement for withstanding acid vapors, which is tough and elastic, is composed of crude rubber, cut fine, 1 part; linseed oil, boiled, 4 parts; fireclay, 6 parts. The rubber is dissolved in carbon disulphide to the consistency of molasses and is then mixed with the oil. Other acid-proof cements are as follows: “Black putty” made by carefully mixing equal portions of china-clay, gas-tar and linseed oil. The china-clay must be well dried by placing it over a boiler or by other means. Barytes cement is composed of pure, finely ground sulfate of barium, and is made into a putty with a solution of silicate of soda. This sets very hard when moderately heated, and is then proof against acids. The gravity of the silicate of soda should be between 1.2 and 1.4, 24 degrees to 42 degrees Baume. If too thin, it does not hold; and when thicker than 1.4, it expands and breaks.

Gasket Compositions.—Almost any cementing substance may be used with rings of asbestos, etc., for gaskets, but some are especially adapted for the purpose. Asphalt, tar, petroleum residuum and soft or hard pitch are recommended. Silicate of soda is much used, and is sometimes advantageously mixed with casein, fine sand, clay, carbonate of lime, caustic lime, magnesia, oxides of heavy metals, such as lead, zinc, iron and powdered

barytes. A few mixtures that might be selected are: Silicate of soda and asbestos; silicate of soda, asbestos and slaked lime; silicate of soda and fine sand; silicate of soda and fireclay.

Machinists Cements.—These are also known as red and white leads. The red lead is often diluted with an equal bulk of silica or other inert substance to make it less powdery. The best way to do this is to add rubber or gutta-percha to the oil as follows: Linseed oil, 6 parts, by weight; rubber or gutta-percha, 1 part by weight. The rubber or gutta-percha is dissolved in sufficient carbon disulphide to give it the consistency of molasses, mixed with the oil, and left exposed to the air for about twenty-four hours. The red lead is then mixed to a putty. Oxide of iron makes a less brittle cement than red lead.

Leather Cements.—a) Equal parts of good hide glue and American isinglass, softened in water for ten hours and then boiled with pure tannin until the whole mass is sticky. The surface of the joint should be roughened and the cement applied hot.

b) 1 pound of finely shredded gutta-percha digested over a water-bath with 10 pounds of benzol, until dissolved, and 12 pounds of linseed oil varnish stirred in.

c) 7 $\frac{1}{2}$ pounds of finely shredded india-rubber is completely dissolved in 10 pounds of carbon disulphide by treating while hot; 1 pound of shellac and 1 pound of turpentine are added, and the hot solution heated until the two latter ingredients are also dissolved.

d) another leather cement is as follows: gutta-percha, 8 ounces; pitch, 1 ounce; shellac, 1 ounce; sweet oil, 1 ounce. These are melted together.

e) still another is as follows: fish glue is soaked in water twenty-four hours, allowed to drain for a like period, boiled well, and a previously melted mixture of 2 ounces of rosin and $\frac{1}{2}$ ounce of boiled oil is added to every two pounds of glue solution.

Iron and Stone Cements.—When finely divided iron, such as filings or cast iron borings that have been powdered, is mixed with an oxidizing agent, such as manganese dioxide, or a substance electro-negative to iron, such as sulphur, in a good conducting solution like salt or sal-ammoniac, galvanic action sets in very rapidly and the iron swells, by forming iron oxide, and cements the mass together. It is best diluted with Portland cement, the proportions being as follows: iron filings, 40 parts; manganese dioxide or flowers of sulphur, 10 parts; sal-ammoniac, 1 part; Portland cement, 23 to 40 parts; water to form a paste. A hard stone-like composition is made as follows: zinc oxide, 2 parts; zinc chloride, 1 part; water to make a paste. Magnesium oxide and chloride may also be used in like proportions. When used in considerable quantity, this cement is mixed with powdered stone, for reasons of economy, the proportions depending upon the character of the work.

Cement Proof to Hydrocarbon Gases.—Compositions of plaster and cement, the former setting more quickly, are used; also compositions of casein, such as finely powdered casein, 2 parts; fresh slaked lime, 50 parts; fine sand, 50 parts. Water is added, when used, to form a thick mass. Various mixtures of silicate of soda are employed in which the thick silicate is absorbed in some inert material such as clay, sand or asbestos.

Cements Proof to Chlorine.—The best and only reliable compositions are a few made with Portland cement, and the following is used for electrolytic and chemical plants: powdered glass, 1 part; Portland cement, 1 part; silicate of soda, 1 part; a small amount of powdered slate. This lute withstands acids and alkalies, as well as the influences of chlorine. Linseed oil made into a paste with fireclay serves for a time.

Elastic Cements.—The various cements containing rubber are elastic, if the rubber is in a predominating amount; many containing boiled linseed oil and the hektograph composition already mentioned are quite elastic. The rubber and linseed-oil cement, given in *Acid-proof Cements* on page 2906, is very tough and useful for nearly all purposes except when oil vapors are to be confined. The most useful single rubber lute is probably the so-called Hart's india-rubber cement. Equal parts of raw linseed oil and pure masticated rubber are digested together by heating, and this mixture is made into a stiff putty with fine "paper stock" asbestos. It is more convenient, however, to dissolve the rubber first in carbon disulphide, and, after mixing the oil with it, to let the solvent evaporate spontaneously.

General Purposes.—Plaster-of-paris, especially when mixed with straw, flush trimmings, hair, broken stone, etc., and used according to temperature strain and other conditions, is one of the most useful preparations for general purposes. A putty of flour and molasses is a good composition to keep in a works ready for quick application when needed. It serves, for a time, almost any purpose at moderate temperatures. Casein compositions have great strength. the white of an egg made into a paste with slaked lime is strong and efficient, but must be used promptly on account of its quick setting qualities.

Marine Glue.—This can be purchased almost as cheaply as made. It consists of crude rubber, 1 part; shellac, 2 parts; pitch, 3 parts. The rubber must first be dissolved in carbon disulphide or turpentine before mixing with the heated combination of the other two ingredients.

Acid-proof Lining.—A lining for protecting tanks from the influence of acids is made from a mixture consisting of 75 parts (by weight), of pitch; 9 parts plaster-of-paris; 9 parts ochre; 15 parts beeswax; and 3 parts litharge. The tanks are covered on the inside with a thick coat of this mixture.

Cements for Pipe Joints.—A strong cement which is oil-proof, waterproof, and acid-proof, consists of a stiff paste of glycerin and litharge. These form a chemical combination which sets in a few minutes. If a little water is added, it sets more slowly, which is often an advantage. This cement is mixed when required for use.

Mixture for Threaded Pipe Joints: A good material to apply to pipe threads before making up the joints, in order to obtain a tight joint that will resist the action of gases or liquids, is made of red lead mixed with pure boiled linseed oil. This mixture has been widely used and is very satisfactory. It should have a heavy fluid-like consistency, and if applied to a clean, well-cut thread will give an excellent joint.

Shellac for Pipe Connections: Shellac has proved to be a very satisfactory substitute for lead in sealing air and gas pipe connections. It is applied with a brush to the joints and hardens very rapidly, and being brittle, the pipes can be readily disconnected.

Graphic, Litharge, Chalk Cement: A good cement for use in making steam pipe joints is made in the following manner: Grind and wash in clean cold water 15 parts of chalk and 50 parts of graphite; mix the two together thoroughly and allow to dry. When dry regrind to a fine powder, to which add 20 parts of ground litharge and mix to a stiff paste with 15 parts of boiled linseed oil. The preparation may be set aside for future use, as it will remain plastic for a long time if placed in a cool place. It is applied to the joint packing as any ordinary cement.

White and Red Lead Mixture: Mix in ordinary white lead, enough powdered red lead to make a paste the consistency of putty. Spread this mixture on the joint, and when it hardens, the joint will be water tight. This mixture was used on stand-pipe flanges after testing all kinds of rubber gaskets without success. The mixture hardened and made a tight joint, never leaking afterward.

Adhesives

Adhesives Bonding.—By strict definition, an adhesive is any substance that fastens or bonds materials to be joined (adherends) by means of surface attachment. However, besides bonding a joint, an adhesive may serve as a seal against attack by or passage of foreign materials. When an adhesive performs both bonding and sealing functions, it is usually called an adhesive sealant.

Where the design of an assembly permits, bonding with adhesives can replace bolting, welding, and riveting. When considering other fastening methods for thin cross-sections, the joint loads might be of such an unacceptable concentration that adhesives bonding may provide the only viable alternative. Properly designed adhesive joints can minimize or eliminate irregularities and breaks in the contour of an assembly. Adhesives can also serve

as dielectric insulation. An adhesive with dielectric properties can act as a barrier against galvanic corrosion when two dissimilar metals such as aluminum and magnesium are joined together. Conversely, adhesive products are available which also conduct electricity.

An adhesive can be classified as structural or non-structural. Agreement is not universal on the exact separation between both classifications. But, in a general way, an adhesive can be considered structural when it is capable of supporting heavy loads; non-structural when it cannot. Most adhesives are found in liquid, paste, or granular form, though film and fabric-backed tape varieties are available. Adhesive formulations are applied by brush, roller, trowel, or spatula. If application surfaces are particularly large or if high rates of production are required, power-fed flow guns, brushes, or sprays can be used.

The hot-melt adhesives are relatively new to the assembly field. In general, they permit fastening speeds that are much greater than water- or solvent-based adhesives. Supplied in solid form, the hot-melts liquefy when heated. After application, they cool quickly, solidifying and forming the adhesive bond. They have been used successfully for a wide variety of adherends, and can greatly reduce the need for clamping and lengths of time for curing storage.

If an adhesive bonding agent is to give the best results, time restrictions recommended by the manufacturer, such as shelf life and working life must be observed. The shelf life is considered as the period of time an adhesive can be stored after its manufacture. Working or "pot" life is the span of time between the mixing or making ready of an adhesive, on the job, and when it is no longer usable.

The actual performance of an adhesive-bonded joint depends on a wide range of factors, many of them quite complex. They include: the size and nature of the applied loads; environmental conditions such as moisture or contact with other fluids or vapors; the nature of prior surface treatment of adherends; temperatures, pressures and curing times in the bonding process.

A great number of adhesives, under various brand names, may be available for a particular bonding task. However, there can be substantial differences in the cost of purchase and difficulties in application. Therefore, it is always best to check with manufacturers' information before making a proper choice. Also, testing under conditions approximating those required of the assembly in service will help assure that joints meet expected performance.

Though not meant to be all-inclusive, the information which follows correlates classes of adherends and some successful adhesive compositions from the many that can be readily purchased.

Bonding Metal: Epoxy resin adhesives perform well in bonding metallic adherends. One type of epoxy formulation is a two-part adhesive which can be applied at room temperature. It takes, however, seven days at room temperature for full curing, achieving shear strengths as high as 2500 psi (17.2 MPa). Curing times for this adhesive can be greatly accelerated by elevating the bonding temperature. For example, curing takes only one hour at 160°F (71°C).

A structural adhesive-filler is available for metals which is composed of aluminum powder and epoxy resin. It is made ready by adding a catalyst to the base components, and can be used to repair structural defects. At a temperature of 140°F (60°C) it cures in approximately one hour. Depending on service temperatures and design of the joint, this adhesive-filler is capable of withstanding flexural stresses above 10,000 psi (69 MPa), tension above 5,000 psi (34 MPa), and compression over 30,000 psi (207 MPa).

Many non-structural adhesives for metal-to-metal bonding are also suitable for fastening combinations of types of materials. Polysulfide, neoprene, or rubber-based adhesives are used to bond metal foils. Ethylene cellulose cements, available in a selection of colors, are used to plug machined recesses in metal surfaces, such as with screw insets. They harden within 24 hours. Other, stronger adhesive fillers are available for the non-structural patch-

ing of defects in metallic parts. One variety, used for iron and steel castings, is a cement that combines powdered iron with water-activated binding agents. The consistency of the prepared mix is such that it can be applied with a trowel and sets within 24 hours at room temperature. The filler comes in types that can be applied to both dry and wet castings, and is able to resist the quick changes of temperature during quenching operations.

Polyester cement can replace lead and other fillers for dents and openings in sheet metal. One type, used successfully on truck and auto bodies, is a two-part cement consisting of a paste resin that can be combined with a paste or powder extender. It is brushed or trowelled on, and is ready for finishing operations in one hour.

Adhesives can be used for both structural and non-structural applications which combine metals with non-metals. Structural polyester-based adhesives can bond reinforced plastic laminates to metal surfaces. One type has produced joints, between glass reinforced epoxy and stainless steel, that have tensile strengths of over 3000 psi (21 MPa). Elevated temperature service is not recommended for this adhesive. However, it is easily brushed on and bonds under slight pressure at room temperature, requiring several days for curing. The curing process accelerates when heat is added in a controlled environment, but there results a moderate reduction in tensile strength.

Low-density epoxy adhesives are successful in structurally adhering light plastics, such as polyurethane foam, to various metals. Applied by brush or spatula, the bonds cure within 24 hours at room temperatures

Metals can be bonded structurally to wood with a liquid adhesive made up of neoprene and synthetic resin. For the best surface coverage, the adhesive should be applied in a minimum of two coats. The joints formed are capable of reaching shear stresses of 125 psi, and can gain an additional 25 percent in shear strength with the passage of time. This adhesive also serves as a strong, general purpose bonding agent for other adherend combinations, including fabrics and ceramics.

For bonding strengths in shear over 500 psi (3.4 MPa) and at service temperatures slightly above 160°F (71°C), one- and two-part powder and jelly forms of metal-to-wood types are available.

Besides epoxy formulations, there are general purpose rubber, cellulose, and vinyl adhesives suitable for the non-structural bonding of metals to other adherends, which include glass and leather. These adhesives, however, are not limited only to applications in which one of the adherends is metal. The vinyl and cellulose types have similar bonding properties, however the vinyls are less flammable and are weaker in resistance to moisture than the comparable cellulose. Rubber-based adhesives, in turn, have good resistance to moisture and lubricating oil. They can form non-structural bonds between metal and rubber.

One manufacturer has produced an acrylic-based adhesive that is highly suitable for rapidly bonding metal with other adherends at room temperature. For some applications it can be used as a structural adhesive, in the absence of moisture and high temperature. It cures within 24 hours and can be purchased in small bottles with dispenser tips.

A two-part epoxy adhesive is commercially available for non-structural bonding of joints or for patchwork in which one of the adherends is metal. Supplied in small tubes, it performs well even when temperatures vary between -50° to 200°F (-46° to 93°C). However, it is not recommended for use on assemblies that may experience heavy vibrations.

Bonding Plastic: Depending on the type of resin compound used in its manufacture, a plastic material can be classified as one of two types: a thermoplastic or a thermoset.

Thermoplastic materials have the capability of being repeatedly softened by heat and hardened by cooling. Common thermoplastics are nylon, polyethylene, acetal, polycarbonate, polyvinyl chloride, cellulose nitrate and cellulose acetate. Also, solvents can easily dissolve a number of thermoplastic materials. Because of these physical and chemical characteristics of thermoplastics, heat or solvent welding may in many instances offer a better bonding alternative than adhesives.

Thermoplastics commonly require temperatures between 200° and 400°F (93° and 204°C) for successful heat welding. However, if the maximum temperature limit for a particular thermoplastic formulation is exceeded, the plastic material will experience permanent damage. Heat can be applied directly to thermoplastic adherends, as in hot-air welding. More sophisticated joining techniques employ processes in which the heat generated for fusing thermoplastics is activated by electrical, sonic, or frictional means.

In the solvent welding of thermoplastics, solvent is applied to the adherend surfaces with the bond forming as the solvent dries. Some common solvents for thermoplastics are: a solution of phenol and formic acid for nylon; methylene chloride for polycarbonate; and methyl alcohol for the cellulose.

Many adhesive bonding agents for thermoplastics are “dope” cements. Dope or solvent cements combine solvent with a base material that is the same thermoplastic as the adherend. One type is used successfully on polyvinyl chloride water (PVC) pipe. This liquid adhesive, with a polyvinyl chloride base, is applied in at least two coats. The pipe joint, however, must be closed in less than a minute after the adhesive is applied. Resulting joint bonds can resist hydrostatic pressures over 400 psi (28 MPa), for limited periods, and also have good resistance to impact.

Previously mentioned general purpose adhesives, such as the cellulose, vinyls, rubber cements, and epoxies are also used successfully on thermoplastics.

Thermoset plastics lack the fusibility and solubility of the thermoplastics and are usually joined by adhesive bonding. The phenolics, epoxies, and alkyds are common thermoset plastics. Epoxy-based adhesives can join most thermoset materials, as can neoprene, nitrile rubber, and polyester-based cements. Again, these adhesives are of a general purpose nature, and can bond both thermoplastics and thermosets to other materials which include ceramics, fabric, wood, and metal.

Bonding Rubber: Adhesives are available commercially which can bond natural, butyl, nitrile, neoprene, and silicone rubbers. Natural and synthetic rubber cements will provide flexible joints; some types resist lubricating and other oils. Certain general purpose adhesives, such as the acrylics or epoxies, can bond rubber to almost anything else, though joints will be rigid. Depending on the choice of adhesive as well as adherend types, the bonds can carry loadings that vary from weak non-structural to mild structural in description. One type of natural rubber with a benzene-naphtha solvent can resist shear stresses to 1252.5 psi (83 kPa).

Bonding Wood: Animal glues, available in liquid and powder form, are familiar types of wood-to-wood adhesives, commonly used in building laminated assemblies. Both forms, however, require heavy bonding pressures for joints capable of resisting substantial loadings. Also, animal glues are very sensitive to variations in temperature and moisture.

Casein types of adhesive offer moderate resistance to moisture and high temperature, but also require heavy bonding pressures, as much as 200 psi, for strong joints. Urea resin adhesives also offer moderate weather resistance, but are good for bonding wood to laminated plastics as well as to other wooden adherends. For outdoor service, under severe weather conditions, phenol-resorcinol adhesives are recommended.

Vinyl-acetate emulsions are excellent for bonding wood to other materials that have especially non-porous surfaces, such as metal and certain plastic laminates. These adhesives, too, tend to be sensitive to temperature and moisture, but are recommended for wooden pattern making.

Rubber, acrylic, and epoxy general-purpose adhesives also perform well with wood and other adherend combinations. Specific rubber-based formulations resist attack by oil.

Fabric and Paper Bonding: The general purpose adhesives, which include the rubber cements and epoxies previously mentioned, are capable of bonding fabrics together and fabrics with other adherend materials. A butadiene-acrylonitrile adhesive, suitable also for fastening metals, glass, plastic, and rubber, forms joints in fabric that are highly resistant to

oil and which maintain bonding strength at temperatures up to 160°F (70°C). This adhesive, however, requires a long curing period, the first few hours of which are at an elevated temperature.

Commonly, when coated fabric materials must be joined, the base material forming the suitable adhesive is of the same type as that protecting the fabric. For example, a polyvinyl chloride-based adhesive is acceptable for vinyl-coated fabrics; and neoprene-based cements for neoprene-coated materials.

Rubber cements, gum mucilages, wheat pastes, and wood rosin adhesive can join paper as well as fabric assemblies. Solvent-based rosins can be used on glass and wood also. Rosin adhesives can also be treated as hot-melt adhesives for rapid curing. Generally, the rosins are water resistant, but usually weak against attack by organic solvents.

Sealants

Sealants.—Normally, the primary role of a sealant composition is the prevention of leakage or access by dust, fluid, and other materials in assembly structures. Nevertheless, many products are currently being manufactured that are capable of performing additional functions. For example, though a sealant is normally not an adhesive, there exists a family of adhesive sealants which in varying degrees can bond structural joints as well. Besides resisting chemical attack, some sealant surface coatings can protect against physical wear. Sealants can also dampen noise and vibration, or restrict the flow of heat or electricity. Many sealant products are available in decorative tints that can help improve the appearance of an assembly.

Most sealants tend to be limited by the operating temperatures and pressures under which they are capable of sustained performance. Also, before a suitable choice of sealant formulation is made, other properties have to be examined; these include: strength of the sealant; its degree of rigidity; ease of repair; curing characteristics; and even shelf and working life.

Dozens of manufacturers supply hundreds of sealant compounds, a number of which may fill the requirements for a particular application. The following information, however, lists common uses for sealants, along with types of compositions that have been employed successfully within each category.

Gasket Materials: Silicone rubber gasket compositions are supplied in tubes in a semi-liquid form ready for manual application. They can also be obtained in larger containers for power-fed applications. Suppliers offer a silicone rubber-based composition that can replace preformed paper, cork, and rubber gaskets for many manufacturing operations. This composition has performed successfully in sealing water pumps, engine filter housings, and oil pans. It can also seal gear housings and other joints that require a flexible gasket material that besides resisting shock can sustain large temperature changes. Silicone rubber compositions can withstand temperatures that vary from -100°F to 450°F (-73°C to 232°C).

Gasket tapes, ropes, and strips can also be readily purchased to fit many assembly applications. One type of sealant tape combines a pressure-sensitive adhesive with a strip of silicone-rubber sponge. This tape has good cushioning properties for vibration damping and can stick to metal, plastic, ceramic, and glass combinations.

TFE-based gasketing strips are also available. This non-stick gasketing material can perform at pressures up to 200 psi (1.4 MPa) and temperatures to 250°F (120°C). Because of the TFE base, the strip does not adhere to or gum joint surfaces.

Sealing Pipe Joints: Phenolic-based sealants can seal threaded joints on high-pressure steam lines. One type, that is available in liquid or paste form, resists pressure up to 1200 psi (8.3 MPa) and temperatures to 950°F (510°C). This compound is brushed on and the joint closed and tightened to a torque of 135 in.-lb. (15.3 N m). The connection is then subjected to a 24-hour cure with superheated steam.

The joining and sealing of plastic pipe is covered under the previous adhesives bonding section.

Sulfur-based compounds, though lacking the durability of caulking lead, can be used on bell and spigot sewer pipe. Available in a formulation that can resist temperatures up to 200°F (93°C), one sulfur-based sealant is applied as a hot-melt and allowed to flow into the bell and spigot connection. It quickly solidifies at room temperature, and can develop a joint tensile strength over 300 psi (2.1 MPa).

There are asphalt, coal-tar and plastic-based compositions that can be used on both cast-iron and ceramic bell and spigot pipe. Portland cement mortars also seal ceramic piping.

SURFACE TREATMENTS FOR METALS**Coloring Metals**

General Requirements in the Coloring of Metal Surfaces.—Copper is more susceptible to coloring processes and materials than any of the other metals, and hence the alloys containing large percentages of copper are readily given various shades of yellow, brown, red, blue, purple, and black. Alloys with smaller percentages of copper (or none at all) can be given various colors, but not as easily as if copper were the principal ingredient, and the higher the copper content, the more readily can the alloy be colored. The shades, and even the colors, can be altered by varying the density of the solution, its temperature and the length of time the object is immersed. They can also be altered by finishing the work in different ways. If a cotton buff is used, one shade will be produced; a scratch brush will produce another, etc. Thus to color work the same shade as that of a former lot, all the data in connection with these operations must be preserved so they can be repeated with exactness.

Cleaning Metals for Coloring.—Metal surfaces to be colored chemically must first be thoroughly cleaned. To remove grease from small parts, dip in benzine, ether or some other solvent for the grease. Boil large pieces in a solution of one part caustic soda and ten parts water. For zinc, tin or britannia metal, do not use caustic soda, but a bath composed of one part carbonate of soda or potash and ten parts water. After boiling, wash in clean water. Do not touch the clean surfaces with the fingers, but handle the objects by the use of tongs or wires.

Pickling Solutions or Dips for Coloring.—The grease removal should be followed by chemical cleansing, which principally serves the purpose of removing the greenish or brownish films which form on copper, brass, bronze, etc. The composition of the bath or mixture for pickling varies for different metals. For copper and its alloys, a mixture of 100 parts concentrated sulphuric acid (66 degrees Baume and 75 parts nitric acid (40 degrees Baume is sometimes used. If the metal is to be given a luster instead of a mat or dull finish, add about 1 part common salt to 100 parts of the pickling solution, by weight. A better dip for a mat surface consists of 90 parts nitric acid (36 degrees Baume 45 parts concentrated sulphuric acid, 1 part salt, and from 1 to 5 parts of sulphate of zinc, by weight. The composition of copper-zinc alloys will produce different color tones in the same dip and will affect the results of chemical coloring. After pickling, washing in water is necessary.

Another good method of removing these films is to soak the work in a pickle composed of spent aquafortis until a black scale is formed, and then dip it for a few minutes into a solution of 64 parts water, 64 parts commercial sulphuric acid, 32 parts aquafortis, and 1 part hydrochloric acid. After that the work should be thoroughly rinsed several times with distilled water.

Coloring Brass.—Polished brass pieces can be given various shades from golden yellow to orange by immersing them for a certain length of time in a solution composed of 5 parts, by weight, of caustic soda, 50 parts water and 10 parts copper carbonate. When the desired shade is reached, the work must be well washed with water and dried in sawdust. Golden yellow may be produced as follows: Dissolve 100 grains lead acetate in 1 pint of water and add a solution of sodium hydrate until the precipitate which first forms is re-dissolved; then add 300 grains red potassium ferro-cyanide. With the solution at ordinary temperatures, the work will assume a golden yellow, but heating the solution darkens the color, until at 125 degrees F. it has changed to a brown.

To Produce a Rich Gold Color.—Brass can be given a rich gold color by boiling it in a solution composed of 2 parts, by weight, of saltpeter, 1 part common salt, 1 part alum, 24 parts water and 1 part hydrochloric acid. Another method is to apply a mixture of 3 parts alum, 6 parts saltpeter, 3 parts sulphate of zinc, and 3 parts common salt. After applying

this mixture the work is heated over a hot plate until it becomes black, after which it is washed with water, rubbed with vinegar, and again washed and dried.

White Colors or Coatings.—The white color or coating that is given to such brass articles as pins, hooks and eyes, buttons, etc., can be produced by dipping them in a solution made as follows: Dissolve 2 ounces fine-grain silver in nitric acid, then add 1 gallon distilled water, and put this into a strong solution of sodium chloride. The silver will precipitate in the form of chloride, and must be washed until all traces of the acid are removed. Testing the last rinse water with litmus paper will show when the acid has disappeared; then mix this chloride of silver with an equal amount of potassium bitartrate (cream of tartar), and add enough water to give it the consistency of cream. The work is then immersed in this solution and stirred around until properly coated, after which it is rinsed in hot water and dried in sawdust.

Silvering.—A solution for silvering, that is applicable to such work as gage or clock dials, etc., can be made by grinding together in a mortar 1 ounce of very dry chloride of silver, 2 ounces cream of tartar, and 3 ounces common salt, then add enough water to obtain the desired consistency and rub it onto the work with a soft cloth. This will give brass or bronze surfaces a dead-white thin silver coating, but it will tarnish and wear if not given a coat of lacquer. The ordinary silver lacquers that can be applied cold are the best. Before adding the water, the mixture, as it leaves the mortar, can be kept a long time if put in very dark colored bottles, but if left in the light it will decompose.

To Give Brass a Green Tint.—One solution that will produce the Verde antique, or rust green, is composed of 3 ounces crystallized chloride of iron, 1 pound ammonium chloride, 8 ounces verdigris, 10 ounces common salt, 4 ounces potassium bitartrate and 1 gallon of water. If the objects to be colored are large, the solution can be put on with a brush. Several applications may be required to give the desired depth of color. Small work should be immersed and the length of time it remains in the solution will govern the intensity of the color. After immersion, stippling the surface with a soft round brush, dampened with the solution, will give it the variegated appearance of the naturally aged brass or bronze.

Blackening Brass.—There are many different processes and solutions for blackening brass. Trioxide of arsenic, white arsenic or arsenious acid are different names for the chemical that is most commonly used. It is the cheapest chemical for producing black on brass, copper, nickel, German silver, etc., but has a tendency to fade, especially if not properly applied, although a coat of lacquer will preserve it a long time. A good black can be produced by immersing the work in a solution composed of 2 ounces white arsenic, 5 ounces cyanide of potassium, and 1 gallon of water. This should be boiled in an enamel or agate vessel, and used hot. Another cheap solution is composed of 8 ounces of sugar of lead, 8 ounces hyposulphite of soda and 1 gallon of water. This must also be used hot and the work afterwards lacquered to prevent fading. When immersed, the brass first turns yellow, then blue and then black, the latter being a deposit of sulphide of lead.

Preservation of Color.—After a part has been given the desired color, it is usually washed in water and then dried with clean sawdust. The colored surfaces of alloys are commonly protected and preserved by coating with a colorless lacquer, such as japan lacquer. Small parts are coated by dipping, and large ones by rubbing the lacquer on. The lacquer is hard after drying, and insoluble in most fluids; hence, it can be washed without injury.

Niter Process of Bluing Steel.—The niter process of bluing iron and steel is as follows: The niter or nitrate of potash (often called saltpeter) is melted in an iron pot and heated to about 600 degrees F. The parts to be blued are cleaned and polished and then immersed in the molten niter until a uniform color of the desired shade has been obtained. This requires only a few seconds. The articles are then removed and allowed to cool, after which the adhering niter is washed off in water. Parts which will not warp may be immersed immediately after removing from the niter bath. After cleaning, dry in sawdust, and then apply some suitable oil, such as linseed, to prevent rusting. To secure uniform coloring, a pyrom-

eter should be used to gage the temperature of the niter, because a higher heat than 600 degrees F. will produce a dark color, whereas a lower heat will give a lighter shade.

Bluing Steel by Heat-treatment.—Polished steel parts can be given a blue color by heating in hot sand, wood ashes, or pulverized charcoal. Place the substance in an iron receptacle and stir constantly, while heating, in order to heat uniformly. Heat just hot enough to char a pine stick. The parts to be blued must be absolutely free from grease. They are placed in the heated substance until the desired color is obtained. Further coloring is then checked by immersing in oil. Small parts are sometimes heated by a Bunsen burner or by laying upon a heated plate. For a light blue color, heat in sand or wood ashes, and for a dark blue, use pulverized charcoal. The quality of the color depends largely upon the fineness of the finish. Still another method of coloring by heat is to immerse the parts in a molten bath of potassium nitrate and sodium nitrate. The coloring is then checked by plunging the work into boiling water.

Blue-black Finish.—To obtain a blue-black finish on small steel parts, use a mixture of 16 parts, by weight, of saltpeter and 2 parts of black oxide of manganese. This mixture is heated to a temperature of 750 degrees F. and the objects are immersed in it. The oxide of manganese is deposited on the work and must, therefore, be frequently replenished in the mixture.

Black Finish.—To obtain a black rust-protecting finish on hardened parts, temper, after hardening, in "heavy" cylinder oil; then immediately place the part with the oil on it in an oven having a temperature of from 300 to 350 degrees F. Remove the work in from to 8 minutes, when the black finish is baked onto it.

Gun Metal Finish.—Several different chemical solutions have been used successfully for giving steel a gun metal finish or black color. Among these are the following:

- 1) Bismuth chloride, one part; copper chloride, one part; mercury chloride, two parts; hydrochloric acid, six parts; and water, fifty parts.
- 2) Ferric chloride, one part; alcohol, eight parts; and water, eight parts.
- 3) Copper sulphate, two parts; hydrochloric acid, three parts; nitric acid, seven parts; and perchloride of iron, eighty-eight parts.

Other solutions have been prepared from nitric ether, nitric acid, copper sulphate, iron chloride, alcohol and water and from nitric acid, copper sulphate, iron chloride and water. The method of applying these and finishing the work is practically the same in all cases.

The surface is given a very thin coating with a soft brush or sponge that has been well squeezed, and is then allowed to dry. The work is then put in a closed retort to which steam is admitted and maintained at a temperature of about 100 degrees F., until the parts are covered with a slight rust. They are then boiled in clean water for about fifteen minutes and allowed to dry. A coating of black oxide will cover the surface, and this is scratch brushed. After brushing, the surface will show a grayish black. By repeating the sponging, steaming and brushing operations several times, a shiny black lasting surface will be obtained. For the best finishes, these operations are repeated as many as eight times.

Another process employs a solution of mercury chloride and ammonium chloride which is applied to the work three times and dried each time. A solution of copper sulphate, ferric chloride, nitric acid, alcohol and water is then applied three times and dried as before. A third solution of ferrous chloride, nitric acid and water is applied three times, and the work is boiled in clean water and dried each time. Finally, a solution of potassium chloride is applied and the work boiled and dried three times. The work is then scratch brushed and given a thin coating of oil. Ordnance for the French Government is treated in this way. The above methods are applicable to hardened and tempered steels, as a temperature of 100 degrees F. does not affect the hardness of the steel. For steels that will stand 600 degrees temperature without losing the desired hardness, better and much cheaper methods have been devised.

The American Gas Furnace Co. has developed a process employing a furnace with a revolving retort. The work is charged in this, together with well-burnt bone. A chemical solution that gasifies when it enters the furnace is then injected into this retort while the work is heated to the proper temperature. This solution has been named "Carbonia." The color does not form a coating on the outside, as with the other processes, but a thin layer of the metal itself is turned to the proper color. By varying the temperature of the furnace, the time the work is in it, and the chemical, different colors can be produced from light straw to brown, blue, purple and black, or gun metal finish. Rough or sand-blasted surfaces will have a frosted appearance, while smooth polished surfaces will have a shiny brilliant appearance.

Browning Iron and Steel.—A good brown color can be obtained as follows: Coat the steel with ammonia and dry it in a warm place; then coat it with muriatic or nitric acid and dry it in a warm place; then place the steel in a solution of tannin or gallic acid and again dry it. The color can be deepened by placing the work near the fire, but it should be withdrawn the minute the desired shade is reached or it will turn black.

To Produce a Bronze Color.—A bronze-like color can be produced by exposing iron or steel parts to the vapors of heated aquaregia, dipping them in melted petroleum jelly, and then heating them until it begins to decompose, when it is wiped off with a soft cloth. Another method of producing this bronze-brown color is to slightly heat the work, evenly cover the surfaces with a paste of antimony chloride (known as "bronzing salt"), and let the object stand until the desired color is obtained. The paste can be made more active by adding a little nitric acid.

To Produce a Gray Color.—A gray color on steel can be obtained by immersing the work in a heated solution of ten grains of antimony chloride, ten grains of gallic acid, 400 grains of ferric chloride and five fluid ounces of water. The first color to appear is pale blue, and this passes through the darker blues to the purple, and, finally, to the gray. If immersed long enough, the metal will assume the gray color, but any of the intermediate colors may be produced. When used cold, this is also one of the bronzing solutions.

Mottled Coloring.—Mottled colors on steel can be produced by heating the objects to a good cherry-red for several minutes in cyanide of potassium, then pouring the cyanide off, and placing the receptacle containing the work back on the tire for five minutes. The contents are then quickly dumped into clean water. To heighten the colors, boil afterward in water and oil.

Coppering Solution.—A coppering solution for coating finished surfaces in order that lay-out lines may be more easily seen, is composed of the following ingredients: To 4 ounces of distilled water (or rain water) add all the copper sulphate (blue vitriol) it will dissolve; then add 10 drops of sulphuric acid. Test by applying to a piece of steel, and, if necessary, add four or five drops of acid. The surface to be coppered should be polished and free from grease. Apply the solution with clean waste, and, if a bright copper coating is not obtained, add a few more drops of the solution; then scour the surface with fine emery cloth, and apply rapidly a small quantity of fresh solution.

White Coatings for Laying Out Lines.—Powdered chalk or whiting mixed with alcohol is commonly used for coating finished metal surfaces preparatory to laying out lines for machining operations. Alcohol is preferable to water, because it will dry quicker and does not tend to rust the surface. This mixture can be applied with a brush and is more convenient than a coppering solution for general work. For many purposes, the surface can be coated satisfactorily by simply rubbing dry chalk over it.

To Produce Gray Colors.—A solution of 1 ounce of arsenic chloride in 1 pint of water will produce a gray color on brass, but if the work is left in this solution too long it will become black. The brass objects are left in the bath until they have assumed the correct shade, and are then washed in clean warm water, dried in sawdust and finally in warm air.

Blue and Violet Shades.—To give brass a blue color, dissolve 1 ounce of antimony chloride in 20 ounces of water, and add 3 ounces hydrochloric acid; then warm the work and immerse it in this solution, until the desired blue is obtained. After that wash in clean water and dry in sawdust. A permanent and beautiful blue-black can be obtained by using just enough water to dissolve 2 ounces copper sulphate and then adding enough ammonia to neutralize and make it slightly alkaline. The work must be heated before immersion.

To Give Brass a Green Tint.—One solution that will produce the Verde antique, or rust green, is composed of 3 ounces crystallized chloride of iron, 1 pound ammonium chloride, 8 ounces verdigris, 10 ounces common salt, 4 ounces potassium bitartrate and 1 gallon of water. If the objects to be colored are large, the solution can be put on with a brush. Several applications may be required to give the desired depth of color. Small work should be immersed and the length of time it remains in the solution will govern the intensity of the color. After immersion, stippling the surface with a soft round brush, dampened with the solution, will give it the variegated appearance of the naturally aged brass or bronze.

Etching And Etching Fluids

Etching Fluids for Different Metals.—A common method of etching names or simple designs upon steel is to apply a thin, even coating of beeswax or some similar substance which will resist acid; then mark the required lines or letters in the wax with a sharp-pointed scribe, thus exposing the steel (where the wax has been removed by the scribe point) to the action of an acid, which is finally applied. To apply a very thin coating of beeswax, place the latter in a silk cloth, warm the piece to be etched, and rub the pad over it. Regular coach varnish is also used instead of wax, as a "resist."

An etching fluid ordinarily used for carbon steel consists of nitric acid, 1 part; water, 4 parts. It may be necessary to vary the amount of water, as the exact proportion depends upon the carbon in the steel and whether it is hard or soft. For hard steel, use nitric acid, 2 parts; acetic acid, 1 part. For high-speed steel, nickel or brass, use nitro-hydrochloric acid (nitric, 1 part; hydrochloric, 4 parts). For high-speed steel it is sometimes better to add a little more nitric acid. For etching bronze, use nitric acid, 100 parts; muriatic acid, parts. For brass, nitric acid, 16 parts; water, 160 parts; dissolve 6 parts potassium chlorate in 100 parts of water; then mix the two solutions and apply.

A fluid which may be used either for producing a frosted effect or for deep etching (depending upon the time it is allowed to act) is composed of 1 ounce sulphate of copper (blue vitriol); $\frac{1}{4}$ ounce alum; $\frac{1}{2}$ teaspoonful of salt; 1 gill of vinegar, and 20 drops of nitric acid. For aluminum, use a solution composed of alcohol, 4 ounces; acetic acid, 6 ounces; antimony chloride, 4 ounces; water, 40 ounces.

The National Twist Drill Co. employs the following method for etching on cutters and other tools: The steel is brushed with asphaltum varnish which is allowed to stand until it thickens and hardens to the right degree; then the desired inscription is pressed through the asphaltum with a rubber stamp and the etching fluid (nitrohydrochloric acid or *aquaregia*) is applied with a medicine dropper. Practice and experience are required to judge just when the varnish has dried to the right consistency. A similar method, which has been successfully used for etching names on cutlery, is to coat the surface with gum guaiacum varnish. A rubber stamp having the name or design is then coated with a thin layer of potash solution. When this stamp is applied to the work, the varnish is "cut" by the potash wherever the coated stamp comes into contact with it; the surface is then brushed lightly with water to remove the loosened varnish and expose the lettering or design, which is then etched by applying dilute nitric acid. The rubber-stamp method is a very cheap and rapid process. One method of applying the potash is to press the stamp against a pad soaked with the solution. The action of etching fluids on steels varies somewhat according to the composition, high-carbon and alloy steels being acted upon more slowly than low-carbon steel or wrought iron.

Etching Brass Nameplates.—Etched brass nameplates having a black background are now often used in preference to cast plates, as they are less expensive. The etched plate is produced by coating a flat and polished sheet of brass with a thin layer of bichromated albumen, and exposing it to the light for a few minutes under a glass negative upon which are a number of the desired nameplate designs. (In order to prepare the bichromated albumen, mix together 10 parts of the white of egg with 30 parts of water. A second mixture is then made consisting of 2 parts of potassium bichromate and 58 parts of water. The first mixture composed of the white of egg and water, and the second mixture containing potassium bichromate and water, are next mixed together in a dark room. The bichromated albumen thus obtained should be kept and used in the dark.) When the brass plate is developed, this removes the albumen not exposed to the light (or that which has been protected by the black portions of the negative), and leaves the brass free to be etched. The etching solution will not attack the parts protected by the albumen or “resist.”

The etching is done by a solution of perchlorate of iron, or by making the plate the anode in an acid-copper solution. When the plate has been etched to the required depth, it is washed. If the etched surface is tarnished, as it usually is after drying, a solution made of 2 parts of water and 1 part of muriatic acid should be spread over the surface to remove the stains and leave it clean and uniform. The plate should then be rinsed, but not dried. Then, without removing the resist, it is treated in some manner to produce a black background. When this has been done, the resist is removed and the sheet is cut up to form the individual nameplates, which are then lacquered.

Producing a Black Background.—The use of a black nickel deposit is the best method of producing a black background on etched brass name-plates. This solution does not affect any of the various kinds of resist used, and a large number of plates can be treated in a tank at one time. The black nickel bath is composed of water, 1 gallon; double-nickel salts, 8 ounces; ammonium sulpho-cyanate, 2 ounces; zinc sulphate, 1 ounce. This solution is used cold, with a weak current of about 1 volt. With a greater voltage, the deposit will be streaked and gray. As soon as the deposit is black, remove the plates, rinse, dry and cut to the desired size; then lacquer immediately in order to prevent the brownish discoloration which will otherwise form on the surface of the deposit. This solution can be used for brass, copper, bronze, etc.

Etching Ornamental Designs in Metal.—When metal plates having an ornamental design are required in small quantities, the etching process is sometimes used. The photographic method which is employed for nearly all intricate designs is as follows: The design is first drawn on white paper to any convenient scale, in black and white. A photographic negative is then made, or this may be procured from photo engravers who make a specialty of such work. The blacks and whites must be, respectively, opaque and transparent. This negative is used to print the design on the work to be etched, the metal, in order to take the design, being coated with a sensitized emulsion of bi-chromated albumen which has the property of remaining insoluble in water after exposure to the light. The portions corresponding to the opaque parts of the negative thus wash out in warm water, leaving the metal bare. Just prior to washing, however, the surface is coated with special lithographic ink, by means of a roller. The design is now on the metal, surrounded by a resist of a bi-chromated albumen base covered with a sticky ink. This resist is further reinforced by sprinkling the surface with dragon's blood. The latter is melted by heating and adheres to the resist, but forms a powder on the unprotected surface which can readily be blown off. This resist is effective, provided the etching is not done too deeply. For brass and copper, a strong solution of perchloride of iron is generally preferred as an etching fluid, as this does not attack the resist like strong acids, although its action is comparatively slow. Nitric acid may be used with proper resists. While etching is usually employed for cutting into the surface of the metal, the same process can be used for perforating the design in the plate.

Various acid-resisting materials are used for covering the surfaces of steel rules, etc., prior to marking off the lines on a graduating machine. When the graduation lines are fine

and very closely spaced, as on machinists' scales which are divided into hundredths or sixty-fourths, it is very important to use a thin resist that will cling to the metal and prevent any under-cutting of the acid; the resist should also enable fine lines to be drawn without tearing or crumbling as the tool passes through it. One resist that has been extensively used is composed of about 50 per cent of asphaltum, 25 per cent of beeswax, and, in addition, a small percentage of Burgundy pitch, black pitch, and turpentine. A thin covering of this resisting material is applied to the clean polished surface to be graduated and, after it is dry, the work is ready for the graduating machine. For some classes of work, paraffin is used for protecting the surface surrounding the graduation lines which are to be etched. The method of application consists in melting the paraffin and raising its temperature high enough so that it will flow freely; then the work is held at a slight angle and the paraffin is poured on its upper surface. The melted paraffin forms a thin protective coating.

MANUFACTURING**Welding with Thermit**

Thermit Process.—This process of welding metals is effected by pouring superheated thermit steel around the parts to be united. Thermit is a mixture of finely divided aluminum and iron oxide. This mixture is placed in a crucible and the steel is produced by igniting the thermit in one spot by means of a special powder, which generates the intense heat necessary to start the chemical reaction. When the reaction is once started it continues throughout the entire mass, the oxygen of the iron being taken up by the aluminum (which has a strong affinity for it), producing aluminum oxide (or slag) and superheated thermit steel. ordinarily, the reaction requires from 35 seconds to one minute, depending upon the amount of thermit used. As soon as it ceases, the steel sinks to the bottom of the crucible and is tapped into a mold surrounding the parts to be welded. As the temperature of the steel is about 5400 degrees F., it fuses and amalgamates with the broken sections, thus forming a homogeneous weld.

It is necessary to pre-heat the sections to be welded before pouring, to prevent chilling the steel. The principal steps of the welding operation are, to clean the sections to be welded, remove enough metal at the fracture to provide for a free flow of thermit steel, align the broken members and surround them with a mold to retain the steel, pre-heat by means of a gasoline torch to prevent chilling the steel, ignite the thermit and tap the molten steel into the mold. This process is especially applicable to the welding of large sections. It has been extensively used for welding locomotive frames, broken motor casings, rudder- and stern-posts of ships, crankshafts, spokes of driving wheels, connecting rods, and heavy repair work in general. One of the great advantages of the thermit process is that broken parts can usually be welded in place. For example, locomotive frames are welded by simply removing parts that would interfere with the application of a suitable mold. Thermit is also used for pipe welding, rail welding, and in foundry practice, to prevent the "piping" of ingots.

Preparation of Part to be Welded.—The first step in the operation of thermit welding is to clean the fractured parts and cut away enough metal to insure an unobstructed flow of the molten thermit. The oxy-acetylene or oxy-hydrogen cutting torch is very efficient for this operation. The amount that should be cut away depends upon the size of the work. Assuming that a locomotive frame is to be welded, the space should be about $\frac{3}{4}$ inch wide for a small frame, and 1 inch wide for a large frame. The frame sections are then jacked apart about $\frac{1}{4}$ inch to allow for contraction of the weld when cooling; trammel marks are scribed on each side of the fracture to show the normal length. If the weld is to be made on one member of a double-bar frame, the other parallel member should be heated with a torch to equalize the expansion in both sections and prevent unequal strains.

Mold for Thermit Welding.—The mold surrounding the fractured part should be so arranged that the molten thermit will run through a gate to the lowest part of the mold and rise through and around the parts to be welded into a large riser. The accompanying illustration shows a mold applied to a locomotive frame that is broken between the pedestals at *A*. The thermit steel is poured through gate *B*, and rises into space *C* after passing around and between the ends of frame *F*. The mold must allow for a reinforcing band or collar of thermit steel to be cast around the ends to be welded. Space *G*, for forming this collar, and the opening between the frame ends, must be filled before ramming up the mold. Yellow wax is ordinarily used for this purpose. The shape of this band or collar should be as indicated by the view of the completed weld at *D*. The thickest part is directly over the fracture and the band overlaps the edges of the fracture at least one inch.

WELDING WITH THERMIT

For a frame of average size, the collars are made about 4 inches wide and 1 inch thick at the center, the thickness being increased for comparatively large sections. An opening is also made at *E* for pre-heating the ends to be welded.

Patterns for the riser, pouring and heating gates can be made of wood. The riser *C* should be quite large because the steel that first enters the mold is chilled somewhat by coming into contact with the metal, even when pre-heated. This chilling effect is overcome by using enough thermit steel to force the chilled portion up into the riser and replacing it by metal which has practically the full temperature received during reaction. The mold must be made of a refractory material, owing to the intense heat. The best material is made of one part fire sand, one part fire-clay and one part ground firebrick, thoroughly mixed while dry and moistened just enough to pack well. If these ingredients cannot be obtained, one part fire-clay and one part clean, dry sand may be used. When the mold and box are filled and tamped, the wooden runner and riser patterns are withdrawn. The mold is then ready for the pre-heating and drying operation which causes the wax matrix to melt and run out.

Thermit Required for Welding.—The quantity of thermit required for making a weld can be determined from the cubic contents of the weld. Calculate the cubic contents of the weld and its reinforcement in cubic inches; double this amount to allow for filling the gate and riser, and multiply by 0.56 to get the number of pounds of thermit required. When wax is used for filling, the weight of the thermit can be determined as follows: Weigh the wax supply before and after filling the fracture. The difference in weight (in pounds, or the quantity used, multiplied by 32 will give the weight of thermit in pounds.

Thermit Additions.—When a quantity of more than 10 pounds of thermit is to be used, add 10 per cent of steel punchings (not over $\frac{1}{2}$ inch in diameter) or steel scrap, free from grease, into the thermit powder. If the thermit exceeds 50 pounds, 15 per cent of small mild steel rivets may be mixed with it. One per cent (by weight) of pure manganese and 1 per cent of nickel - thermit should be added to increase the strength of the thermit steel.

Pre-heating — Making a Weld.—The ends to be welded should be red hot at the moment the thermit steel is tapped into the mold. This pre-heating is done, preferably, by a gasoline, compressed-air torch, and, as previously mentioned, it melts the wax matrix used for filling the fracture to form the pattern for the reinforcing band. When the ends have been heated red, quickly remove the torch and plug the pre-heating hole *E* with a dry sand core, backing it up with a few shovelfuls of sand, well packed. The end of the coneshaped crucible should be directly over the pouring gate and not more than 4 inches above it. To start the reaction, place one-half teaspoonful of ignition powder on top of the thermit and ignite with a storm match. It is important that sufficient time be allowed for the completion of the thermit reaction and for fusion of the steel punchings which have been

mixed within the thermit. Within charges containing from 30 to 50 pounds of thermit, the crucible should not be tapped in less than 35 seconds; with charges containing from 50 to 75 pounds, 40 seconds; 75 to 100 pounds, 50 seconds to one minute.

When welding a frame broken as shown in the illustration previously referred to, the screw jack used for forcing the pedestals apart should be turned back somewhat to release the pressure gradually as the weld cools. After pouring, the mold should remain in place as long as possible (preferably 10 or 12 hours) to anneal the steel in the weld, and, in any case, it should not be disturbed for at least two hours after pouring.

When welding a broken spoke in a driving wheel, or a similar part, it is necessary to pre-heat the adjacent spokes in order to prevent undue strains due to expansion and contraction. If a section of a spoke is broken out, it can be cast in, but if the space is over 6 inches long, it is better to insert a piece of steel and make a weld at each end. Owing to the high temperature 5400 degrees F.) and the violent ebullition of thermit during reaction, the crucible must be lined with a very refractory material. The crucibles used for this purpose have a sheet-iron shell and are lined with magnesia.

Filling Shrinkage Holes and Surface Flaws.—The filling of surface flaws in castings and forgings usually requires from 2 to 10 pounds of thermit. To make a weld of this kind, place an open mold around the part to be filled, large enough to overlap it about $\frac{1}{2}$ inch. Clean the hole thoroughly and heat to a red heat by means of a strong blow-torch. Use eighteen ounces of thermit for each cubic inch of space to be filled, but do not use less than two pounds for any one weld. Place a small amount of thermit in the crucible which, in this case, is of a small size for hand use. Ignite the thermit with ignition powder and as soon as it begins to burn, add the remainder, feeding it fast enough to keep the combustion going. When the reaction is completed, quickly pour the slag (which is about three-fourths of the total liquid) into dry sand; then pour the steel into the open mold and sprinkle loose thermit on top to prolong the reaction, as the casting, even when pre-heated, will have a chilling effect on the steel.

Composition of Thermit Steel.—An average analysis of thermit steel is as follows: carbon, 0.05 to 0.10 per cent; manganese, 0.08 to 0.10 per cent; silicon, 0.09 to 0.20 per cent; sulphur, 0.03 to 0.04 per cent; phosphorus, 0.04 to 0.05 per cent; aluminum, 0.07 to 0.18 per cent. The tensile strength is about 65,000 pounds per square inch.

High- and Low-pressure Torches.—The difference between high- and low-pressure welding and cutting torches, according to the generally accepted meaning of the term, is in the pressure of the acetylene. The first oxy-acetylene torches developed by Fouche were of the high-pressure type, using acetylene dissolved in acetone. Later, he developed a low-pressure torch, working on the injector principle, acetylene being drawn into the carburetor chamber where it mixed with the oxygen. The high pressures originally employed in the first torches could not be safely employed with the acetylene produced in generators, because the safe pressure of acetylene in volume should never exceed from 15 to 20 pounds per square inch, and the pressure is limited to 25 pounds per square inch by the Underwriters' Association in the United States: hence, the medium pressure which is in general use was developed. The proportion of oxygen to acetylene varies somewhat in the different torches. Usually from 1.04 to 1.12 times more oxygen is consumed than acetylene.

Welders and cutters should be provided with goggles or spectacles fitted with approved colored lenses that protect the eye from destructive light rays, flying sparks and globules of molten metal.

FORGE SHOP EQUIPMENT**Hammer and Anvil**

Blacksmiths' Anvils.—The quality of an anvil can generally be judged by its ring, a good anvil giving out a clear, sharp sound when struck with a hammer. If soft or defective, the sound will be dull. A good anvil so mounted that it gives out a full volume of sound is easier to work upon than one having a dead ring. Anvils ordinarily vary in weight from 150 to 300 pounds. A mistake is often made in selecting anvils that are too light for the service required. A 300-pound anvil is suitable for almost any kind of machine blacksmithing, and, if of this weight or heavier, it will not move around while in use or need to be strapped to its block. The square hole in the face of an anvil for receiving the cutting and forming tools is called the "hardie hole," and the small round hole near it is called the "pritchel hole." Anvils are usually made with a wrought-iron body to which is welded a hardened steel face.

Setting the Anvil.—The height of an anvil should be such that when standing beside if the knuckles of the hands will just reach the top surface or face. A solid oak block set endwise in the ground is often used as a foundation, but a cast-iron mounting block is preferable as it can easily be moved. The casting should have a fairly broad base, and a pocket at the top for receiving the anvil; a flat block of wood is provided to act as a cushion. An anvil should not be strapped rigidly to its foundation, as this checks the vibration which tends to keep the face free from scales, and renders a high-grade wrought-iron anvil little better than one made of cast iron. When a wooden block is used under the anvil, it is necessary to drive in a few spikes to keep the anvil in place, but these should be so placed that they do not bear directly upon or bind against the corners.

Steam Hammer Rating.—The capacity of a steam hammer or its rating is the weight of the ram and its attached parts, such as the piston and rod. The steam pressure behind the piston is not considered as far as the rating is concerned. For example, a 1000-pound hammer has reciprocating parts of that weight. The steam pressures for operating hammers usually vary from 75 to 100 pounds per square inch.

Capacity of Steam Hammers.—Capacity of a steam hammer or the proper size to use for working iron and steel of a given cross-sectional area can be determined approximately by the following rule: Multiply the area of the largest cross-section to be worked by 80, if of steel, or 60, if of iron, and the product will be the required rating of the hammer in pounds. For example, the capacity of a hammer for working steel billets 5 inches square would be determined as follows: $5 \times 5 = 25$; and $25 \times 80 = 2000$, which is the rating of the hammer in pounds. A hammer rated according to this rule is an economical size to use, although it can, of course, be employed for heavier work.

Power for Operating Steam Hammers.—The boiler horsepower for operating a steam hammer depends upon the service required and the number of hammers in use. Ordinarily, the boiler capacity can be less where there are a number of hammers, because all of the hammers are rarely, if ever, used at the same time; consequently, there is a reserve power; but with a single hammer, especially when in constant service, the boiler capacity should be proportionately greater. For average conditions, the boiler horsepower can be determined approximately by the following rule: Divide the rated capacity of the hammer in pounds by 100, and the quotient will be the boiler horsepower required for continuous operation. For example, if the hammer is rated at 2000 pounds, the boiler horsepower would equal $2000 \div 100 = 20$ H.P. This rule is also applicable in cases where the hammer is not used continually, by estimating the amount of idle time and making suitable allowance, but the boiler capacity must not be reduced to such an extent that there is a decided diminution in the pressure during the working period.

For foundations for steam hammers, see section on "Machinery and Hammer Foundations."

Board Drop-hammers.—This type of hammer is generally considered superior to the steam hammer for producing drop-forgings of small and medium size. When the work is heavy and requires a great deal of "breaking down" or drawing, or even when the forgings are light, but have thin sections that cool quickly, thus requiring sharp, rapid blows, the steam hammer will usually give better results than aboard drop. The capacity of most of the board drop-hammers in use varies from 800 to 1500 pounds; the steam hammers found in drop forging plants usually range from 2000 to 5000 pounds capacity, for handling average work. It does not seem practicable to build board drops larger than 3000 pounds falling weight, and where the forgings are heavy enough to require a capacity over 1500 or 2000 pounds, steam hammers are usually preferred. The latter type is also preferred in some forge shops for all classes of work. It is generally conceded that the cost of operation and repairs is greater for steam hammers, but the latter has a greater output for a given capacity.

The power required for operating board drop-hammers varies considerably with the nature of the work. Very little power is required at the point of "pick up," if the work is practically "die to die;" but when the work is soft and there is no rebound, a great deal more power is required, as the rolls have to pick up a "dead load" from rest and there is tattle kinetic energy in the driving pulleys. When there is a good rebound, with the knock-off properly timed, the board will be moving upward with considerable velocity when engaged by the rolls, and much less power is required. Seasoned maple boards have proved superior to any other kind for board drop-hammers. Paper fiber has been tried with fair results, but at present the cost of this material is too high.

For foundations for drop-hammers, see section on "Machinery and Hammer Foundations."

Forging Presses.—The power of forging presses for the average line of work is approximately as follows: For mild steel at a fair heat, a pressure of from 3 to 5 tons per square inch on the faces of the tools is generally sufficient, but when swages or dies are used, it may be necessary to double these pressures. For the very hardest steels, the pressure required may be as high as 10 or even 15 tons per square inch, but this is an exceptional case. For small forgings, including such parts as can be made from 8-inch square blooms or 12- by 6-inch flats, a press of 300 tons is sufficient, and for larger forgings, such as those used for heavy marine shafts and cranks, a 3000-ton press is generally considered sufficient and can readily handle a 60-inch ingot. The table above indicates, in a general way, the capacity of presses for handling ingots of various diameters.

Table 65. Capacity of Forging Presses

Capacity of Press, Tons	Maximum Diam. of Ingots, Inches	Capacity of Press, Tons	Maximum Diam. of Ingots, Inches
300	10	1500	36
500	14	2000	48
800	20	3000	60
1200	27	4000	72

A press of comparatively small capacity may, with suitable appliances, handle work that is really too heavy for it, but at some sacrifice of speed; for economical operation, there should be ample power. As is generally known, the forging press is superior to the steam hammer for comparatively large forgings, because the hammer tends to spread the surface metal without acting upon the center of the ingot to the required degree. With a press, the forging action goes right to the center of the ingot, as evidenced by the bulging that takes place at the sides, and if there is a cavity in the ingot, forging under the press closes it, whereas a hammer, by spreading the surface metal, may tend to enlarge it. As forgings diminish in size, the difference in favor of the press is less marked. Owing to the recent increase in the operating speed of forging presses, however, they now compete with power hammers in the forging of comparatively light work, and the range of presses has been greatly extended.

Air Pressures and Pipe Sizes for Forges.—Blacksmiths' forges require air pressures varying from $1\frac{1}{2}$ to 6 ounces per square inch. Small forges with the blower close to them are adequately supplied with $1\frac{1}{2}$ ounce pressure. If the blower is some distance away and a long discharge pipe with many bends leads to the forge, even though the latter be small, it may be necessary to carry 3 ounces pressure or more, to overcome the friction in the air ducts. Large forges usually require from 3 to 6 ounces pressure. The table, "Air Pressures and Pipe Sizes for Forges," gives the diameters of discharge mains for various tuyere sizes and numbers of forges.

Table 66. Air Pressures and Pipe Sizes for Forges

American Blower Co.

The Cold Swaging Process.—Cold swaging is a method of reducing or forming steel or other material while cold, by drawing to a point or reducing the diameter, as may be required. This is performed by a machine that causes the work to be struck a large number of successive blows by a pair of dies shaped to give the required form. This process is principally applied to the reduction of wires, rods and tubes, and is the only method by which rolled or plated stock can be reduced without destroying the plating or coating. For this reason, it is largely employed for jewelers' work. It is also extensively used for pointing rods or tubes which are to be drawn. The process is used in the manufacture of needles, bicycle spokes, button hooks, crochet needles, etc.

Forging Machines.—Some forging machines are intended especially for bolt and rivet heading, and others for more general work. The form or shape into which a part is forged is governed by dies of the required shape and also by a heading tool or plunger which bends or upsets the heated bar of metal and forces it into the die impression. The die may have a single impression, or two or three impressions may be required in order to forge the part by successive operations.

Dies for Bolt and Rivet Forging Machines.—Bolt and rivet dies used in forging machines are, as a rule, made from steel containing from 0.60 to 0.80 per cent carbon and are hardened and drawn. The heading tool, which must be tougher than the dies, is generally made from steel containing from 0.40 to 0.50 per cent carbon, and is drawn considerably more than the forming dies.

Dies and Tools Used in Hot-pressed Center-feed Nut Machines.—The dies used in hot-pressed center-feed nut machines are usually made from chilled iron castings, the dies being ground to size. It is claimed that dies made from this material will last fully eight times as long as those made from ordinary carbon steel, but as it is somewhat difficult to obtain the proper amount of chill, many manufacturers use a good grade of open-hearth crucible steel instead. A crucible steel which is found to give good results contains from 0.90 to 1.10 per cent carbon. In many cases, vanadium alloy steel is used for dies for nut forging machines. The composition of vanadium steel for dies varies. Two grades of vanadium tool steel are recommended for forging machine dies by the American Vanadium Co., of Pittsburgh, Pa. One is composed of carbon, 0.50 per cent; chromium, from 0.80 to 1.10 per cent; manganese, from 0.40 to 0.60 per cent; vanadium, not less than 0.16 per cent; silicon, not more than 0.20 per cent. The heat-treatment recommended for this steel is as follows: Heat to 1550 degrees F. and quench in oil; then reheat to from 1425 to 1450 degrees F., and quench in water, submerging the face of the die only.

The second kind of vanadium tool steel recommended has the following analysis: Carbon, from 0.65 to 0.75 per cent; manganese, from 0.40 to 0.60 per cent; vanadium, not less than 0.16 per cent; silicon, not more than 0.20 per cent. The heat-treatment for this steel should be as follows: Heat to 1525 degrees F. and quench in water, with only the face of the die submerged. Ordinary carbon tool steel dies should be drawn to a light straw color.

Bulldozer Dies.—Many of the tools or dies used on bulldozers are made of cast iron, in order to reduce the cost, and those parts of the dies which are subjected to wear are faced with hardened steel plates which may readily be replaced, if necessary. Whenever hot punching or cutting is done, high-speed self-hardening steel should be used for the working members of the tool.

Helve Hammers.—Power hammers of the helve type are adapted especially for relatively light forging operations, particularly when a rapid succession of blows is required. Ordinary helve hammers are usually built in sizes ranging from 15 to 200 pounds, this rating being based upon the weight of the hammer head. Some "upright helve" hammers are made in sizes up to 500 pounds.

Vertical Power Hammers.—Vertical power hammers of the crank- and pneumatically-operated types are used for general forging operations, especially on the lighter classes of work. Power hammers of the vertical type usually range in size from 25 pounds up to 500 pounds.

Efficiency of Forging Hammers.—The Heim method for determining the efficiency of forging hammers is based on the results of numerous tests conducted by allowing an ordinary drop-hammer to fall a predetermined distance upon a pure lead cylinder, the height of which is 1.5 times its diameter. The diameters of the cylinders which have been adopted for use in testing various sizes of hammers (with regard to their falling weight) are given in [Table 67](#). The following formula gives the number of foot-pounds of work done by one blow of the hammer:

$$\text{Work} = 36.75D^3 [8.85A + 13.12(A^2 + A^4)] \text{ foot-pounds}$$

Where D = Diameter of the lead cylinder;

$$A = (H - H_1) \div H$$

H = Original height of the cylinder

H_1 = height of the cylinder after being struck by the hammer.

If the expression inside the brackets in the formula is designated by B , the formula may be expressed in the following form:

$$\text{Work} = 36.75D^3 B$$

After the lead cylinder has been struck by the hammer, the value of A is calculated and the number of foot-pounds of work developed by the hammer is then obtained by taking the value of B from Table 68 and substituting in the formula.

Example: Suppose a 100-kilogram (220-pound) hammer striking 180 blows per minute is allowed to strike a lead cylinder, the original dimensions of which are 50 millimeters (1.97 inch) in diameter by 75 millimeters (2.95 inches) high. After the blow has been struck, the resulting height of the cylinder is 48 millimeters (1.90 inch). From the preceding formula:

$$A = \frac{2.95 - 1.90}{2.95} = 0.35$$

$B = 4.9$, from Table 68

Substituting the values of D and B in the formula for the work done by one blow of the hammer:

$$36.75 \times 1.97^3 \times 4.9 = 1376 \text{ foot-pounds} = \text{work done by one blow.}$$

$$\frac{1376 \times 180}{60} = 4128 \text{ foot-pounds} = \text{work done by one blow.}$$

The maximum power required to drive the hammer is 10.3 horsepower. As one horsepower is equivalent to 550 foot-pounds of work per second, the amount of power consumed by the hammer per second is: $10.3 \times 550 = 5665$ foot-pounds. The efficiency of the is found to be:

$$\text{Efficiency} = \frac{\text{useful work}}{\text{power supplied}} = \frac{4128}{5665} = 72 \text{ percent.}$$

The Heim formula and method of testing may be applied to all types of hammers, but, when used on steam hammers, the test must be made while the hammer is running continuously and not when set to deliver a single blow.

Table 67. Dimensions of Lead Plugs Used for Testing Various Sizes of Hammers

Falling Weight of Hammer		Diameter of Lead Cylinder ^a		Falling Weight of Hammer		Diameter of Lead Cylinder	
Pounds	Kilograms	Inches	Millimeters	Pounds	Kilograms	Inches	Millimeters
66	30	1.18	30	330	150	2.36	60

Machinery and Hammer Foundations

The materials commonly used are concrete, stone, brick, and wood in conjunction with concrete for machines subjected to considerable vertical shock. The principal characteristics of these materials are briefly as follows: Concrete is an ideal foundation material, as it becomes practically one solid piece and is much cheaper than a masonry foundation. Stone, in addition to being strong and durable, has great vibrations absorbing power, but is quite costly. Brick is not so durable as stone, but is cheaper and available everywhere. In building a foundation, provision should be made for the foundation bolts, when these are necessary. Sometimes the bolts are set permanently in the foundation, or they may be placed in pipes and have pockets at the lower ends, thus permitting adjustment or removal, if necessary. The bolts are usually located in the proper position by making a wooden templet in which holes are bored to coincide with the holes in the machine base. The inclination of the sides of a foundation should vary from $1\frac{1}{2}$ to 3 inches per foot from the vertical. The foundation pit should be excavated below the frost line of the locality.

Concrete Foundations.—The timber used for making the forms in which concrete foundations are molded should be about 1 inch thick, dressed on the inner side to give a smooth surface. The form should be braced externally about every $2\frac{1}{2}$ feet, and internally about every foot in height. As the form is being filled, the inside braces can be removed. If pocket molds are used for the lower ends of the bolts, they should be soaked in water two or three hours before using, to prevent their swelling and sticking in the concrete. Do not use concrete that has been mixed over twenty minutes. Ram with hammers weighing about 1 pound per square inch of face area, the ramming being continued until water just shows at the surface.

Fig. 1.

Fig. 2.

Put down the concrete in layers about 6 inches thick and work it onto the form with a shovel, to obtain a smooth, even surface. The foundation may be partly filled with stones about the size of a man's head, placed approximately one foot apart and not less than one foot from the foundation surfaces. These stones should be wet before laying. If the work is stopped at night before completion, make grooves in the surface and when starting the next

day, sprinkle and dust over with dry cement. As soon as the concrete has set, remove the form, as it is much easier to patch when the cement is somewhat "green." Foundations are sometimes "slushed" instead of being rammed. In this case, the concrete is mixed just wet enough so that it cannot be piled up. It is then dumped into the molds and worked in them to prevent air bubbles. The first method gives a more homogeneous structure as there is no chance for the broken stones to settle. When the machine is in position, the space around the foundation bolts may be filled with liquid cement, lead or melted sulphur.

Drop Hammer Foundations.—The following drop-hammer foundations are recommended by the E. W. Bliss Company:

Concrete Foundation: Excavate a hole from 10 to 14 feet deep and from 8 to 12 feet square; build up a block of concrete with tapering sides, as shown in Fig. 63, having a top about 6 to 12 inches wider, all around, than the base of the anvil. Place the anvil in position and wedge it level; then run a thin mixture of concrete the anvil and allow it to set. Next move the wedges and build up a wall of concrete from 4 to 6 inches thick around the anvil. (See Fig. 1 and Fig. 2) This will make the use of bolts unnecessary and the anvil will set solid and will not be likely to shift. Solid concrete makes an excellent foundation that does not deteriorate, as is the case with timber when subjected to dampness from the earth or atmospheric moisture. Another advantage is that it is almost impervious to sparks or hot pieces of metal.

Timber Concrete Foundations: Excavate a hole somewhat larger than the anvil or base of the hammer. At the bottom lay a bed of concrete from 1 to 2 feet thick, as shown in Fig. 2. On this concrete bed place, endwise, Georgia pine timbers 12 by 12 inches by 6 to 8 feet long. These should be securely strapped together by steel bands on the outside fastened with through bolts. The timber base should preferably be a little larger than the anvil. To preserve the timbers coat them with oil of tar or creosote. The tops of the timbers should be dazed off evenly to obtain a level surface for the anvil. Another method of making a foundation of this kind, for small and medium sized hammers, is to put the timbers upon a foot or more of gravel rammed down on a hard-pan bottom. When the timbers, which are also placed endwise and bolted, are in position, the space around the sides is filled with gravel tightly rammed.

Foundation for Steam Hammer.—To secure the greatest efficiency from steam power hammers, the foundations on which they are mounted must be solid concrete resting upon hard-pan has given better results than the combination of heavy wooden beams and concrete often used. When making solid concrete foundations, there should be several inches of cement placed over the concrete, and a cushion of wood, at least 3 inches tuck, between the cement and base of the anvil, to give the necessary resiliency and prevent the concrete from being pulverized by the impact of the blows. In the front and rear of the hammer there should be openings down to the level of the anvil base, so that it can be leveled or adjusted by wedging and grouting with cement, in case it should sag or get out of alignment with the upper parts of the hammer. These openings can be covered with hatches set level with the floor.

Machine and Forge Shop Floor Materials

Machine shop floors are commonly made of wood or concrete. Probably there is no floor for the machine shop as good as one made of selected hard maple, properly laid and supported, as it wears smoothly and evenly. Concrete, however, has its advantages, the most important of which is its fire-resisting qualities. There are few objections to a wooden floor, and from the standpoint of health it is generally considered superior to concrete. Where there is much heat, or large quantities of moisture or chemicals in bulk, wooden floors should not be used. In certain classes of store-rooms, or where there is a likelihood of considerable moisture, as in wash rooms, concrete floors are considered superior to wood.

Concrete and Wooden Floors.—The following information on shop floors and their materials is abstracted from a paper by Mr. L. C. Wason read before the American Society of Mechanical Engineers. While the factor of cost is to be considered first, very often the maintenance and adaptability for the particular Service required is of first importance. The initial cost of a granolithic floor surface is at no disadvantage compared with a wooden floor, as the cost of such a surface laid in the best manner is about equal to the cost of seven-eighths maple flooring. In addition, the granolithic surface is fire-proof and will not decay or disintegrate as the result of moisture, which is one of the weak points of the wooden floor. On the other hand, a wooden floor is more easily repaired than a granolithic surface. In making a comparison between wooden and granolithic floors, it is also necessary to consider the workmanship. With a maple top floor, the wearing quality depends comparatively little on the skill of the one who lays the floor, but with a granolithic finish, the work must be done care fully and intelligently. Among the objections to the granolithic surface, one of the most prominent is the bad effect of a concrete floor upon the health and comfort of the workmen. This is not due to the hardness of the floor, but rather to its heat conductivity. When a workman stands for hours on a concrete floor, the heat of the body is conducted to the floor quite rapidly, which tends to disarrange the circulation and cause physical ailments, such as rheumatism, etc. For men working steadily at machines, and usually in one position, this objectionable feature can be overcome by the use of insulating foot-boards or wooden gratings upon which to stand.

The dust produced by the wear of some granolithic surfaces has proved harmful to delicate machinery, whereas a wooden floor does not of itself produce a dust capable of any appreciable abrasive action. It is possible, however, by gluing battleship linoleum to concrete floors, to obtain many of the advantages of a wooden surface. Linoleum is also an effective insulation against the loss of bodily heat.

High resistance to wear and practically complete dustlessness can be secured in a granolithic surface if properly made. To secure a durable and practically dustless floor, proceed as follows: Do not use sand, as sand grains are quickly broken by abrasion and form dust. The granolithic finish should contain the highest possible proportion of tough stone aggregate. Use stone suitable for macadam road, and of a size that will pass through a half-inch round mesh screen, but use nothing smaller than that passed by a 20-mesh screen. Mix the concrete dry, and of a consistency for making blocks, so that considerable tamping will be required to bring enough water to the surface for troweling. Finally, do the troweling before the mortar sets. Prolonged troweling of a wet mixture brings to the top the "laitance" of the concrete, which is the part incapable of a true set. A top layer of laitance is therefore porous and wears down quickly. Even the fine particles of good cement should not be brought to the surface, as they form a layer which is weakly bonded to the rest of the concrete and wears away rapidly, appearing in the air as dust.

To Prevent Dust on Concrete Floors.—The Aberthaw Construction Co. of Boston, contracting engineers specializing in concrete, recommends the following method of curing a dusty concrete floor: Have the surface entirely dry; then paint it with a mixture of boiled linseed oil thinned with gasoline. Apply several coats, until the oil shows glossy on the top. The theory of this is that the linseed oil, having been boiled, has lost most of its volatile components and is practically permanent. The gasoline thins this down enough so that it will strike into the pores. A little experimenting will show the proper proportions. The thinner it is, the more coats will be required and the deeper it will strike in. A floor that is causing serious trouble from dust can often be cured with very little trouble and expense in this way.

Floors for Forge Shops.—There is considerable difference in opinion as to the best material for blacksmith shop flooring. Wood is too inflammable, bricks crack and break from the heat, cement or concrete has the same objectionable features, and asphalt is out of the question. Perhaps nothing is superior to or cheaper than dirt mixed with ashes. If kept moist by sprinkling at least once a day, it is more comfortable to stand upon than the other mate-

rials mentioned. It is easily repaired and leveled in case holes are worn in it, and is not affected by dropping heavy or hot pieces upon it. The space between the walls and forges, however, may be covered with concrete to facilitate the handle of such appliances as portable surface-plates and vises.

Drop-Forging Dies

Steel for Drop-forging Dies.—Practically all drop-forging dies are made of high-grade open-hearth steel. A 60-point carbon steel is mostly used, although steel as low as 40-point and as high as 85-point carbon is employed in some cases. A special hardening treatment is required for the low-carbon steel, which more than offsets the saving in price, and, except in special cases, there is no advantage in using high-carbon steels, owing to the expense. The average 60-point carbon steel die, if properly hardened, should last for from 15,000 to 40,000 forgings, and sometimes as many as 70,000 forgings can be made from one set of dies. When making dies for large forgings, it is often thought advisable to use 80-point carbon steel, and not harden the dies. This obviates the danger from “checking” or cracking in hardening, and the un-hardened steel is hard enough to resist the tendency to stretch. A steel that is quite high in carbon should always be used for dies that are intended for making forgings from tool steel or any other hard steel.

Allowance for Shrinkage.—When making dies for small cold-trimmed steel forgings, the proper allowance for shrinkage is $\frac{3}{16}$ inch to the foot, or 0.015 inch to the inch. Such forgings are finished at a bright red heat and the rate of shrinkage is considerable. When making dies for hot-trimmed steel forgings of medium and large sizes, the shrinkage allowance is $\frac{1}{8}$ inch to the foot, or 0.010 inch to the inch. Hot-trimmed forgings receive the finishing blow while comparatively cold, and shrink a smaller amount than the cold-trimmed forgings. The foregoing allowances are used for all dimensions of the die impression, such as depth, width or length. The shrinkage allowance for dies to be used in forging bronze or copper is practically the same as that for steel.

Draft Allowance.—The amount of draft in a drop-forging die varies from 3 to 10 degrees. If the die is for a thin forging of uniform section, 3 degrees is ample, but if the forging is deep and has narrow ribs which are apt to stick, at least 7 degrees is necessary. If a die is used for forging a piece that is ring-shaped or has an annular part, the central plug that forms the interior of the ring should have a draft of 10 degrees, because, as the forging cools while being worked, it tends to shrink around the plug and if the draft is insufficient, it will stick in the die. With the foregoing exception, most drop-forging dies have a 7-degree draft. For convenience in laying out, it is well to remember that a 7-degree taper is approximately equal to a $\frac{1}{8}$ -inch taper to the inch, and a 10-degree taper, $\frac{3}{16}$ inch to the inch.

Locating Impression in the Die.—When laying out a drop-forging die, the impression should be located so that the heaviest end of the forging will be at the front of the die-block. This makes the forging easier to handle and also permits the use of a fairly large sprue. There should be at least $1\frac{1}{2}$ inch left all around between the impression and the outside edge of the block. This also holds true for any part of the die, such as the edger, anvil or forming impression. If the forging has a hub or other projection that extends some distance from the main part on one side, the upper or top die should contain this deeper impression.

Obtaining Weight of Forging from Lead Proof.—After the upper and lower dies have been completed, shrinkage allowances and the general finish of the impressions are ordinarily tested by taking a “lead proof,” and by weighing the lead, an approximate idea of the weight of the finished forging can be obtained. Roughly speaking, the finished forging will weigh two-thirds as much as the lead proof. The shrinkage of lead is practically the same as that of steel, so that the finished forging will also measure about the same as the one made of lead. In case of dies for eye-bolts and similar work, this rule must be disregarded, because the plugs that form the central opening will prevent the lead from shrinking natu-

rally. When taking the lead proof, the die impressions are dusted with powdered chalk, and after the dies are clamped together, the molten lead is poured.

Amount of Flash for Drop-forging Dies.—Theoretically, there should be just enough forging metal in a die to fill the impression, and no more, but this is, of course, not practicable, as there is always some stock that must be disposed of after the impression is filled. To take care of this excess metal, dies are relieved all around the impression by milling a flat shallow recess about $\frac{1}{64}$ inch deep and $\frac{5}{8}$ inch wide. These dimensions are for dies of average size; in comparatively large dies this recess or “flash” would be a little deeper and wider. Both the upper and lower dies are flashed in this way. In addition, the upper die is “back-flashed,” which means that there is a deeper recess, sometimes called the “gutter,” milled around the impression at a distance of $\frac{1}{4}$ inch from the impression at every point. This back-flash is $\frac{3}{64}$ inch deep and acts as a relief for the excess metal after it has been squeezed from the flash proper. Only the finishing impression is provided with a flash and back-flash.

The Break-down of Drop-forging Dies.—The width of section used as a break-down (also known as the edger or side cut) should be enough wider than the forging to give plenty of room for the work of forging. A forging 1 inch thick should have a break-down $1\frac{1}{2}$ inch wide, and about the same proportions should be followed for forgings of other widths. The break-down should have a section corresponding with the gate and sprue of the die impression, but it should be made slightly longer, so that the forging will not be stretched when struck in the impression.

Hardening Drop-forging Dies.—Dies to be carburized should always be packed for hardening in cast-iron or sheet-iron boxes containing a mixture of fresh bone and charcoal. The ordinary mixture is half bone and half charcoal. More bone gives greater hardness and more charcoal, less hardness, for a given heat; hence, the proportions should be varied according to requirements. The die should be packed face down on a one- or two-inch layer of this mixture and be settled so that the impression is filled. Sometimes the face is coated, before packing, with a thick paste of linseed oil and powdered bone-black, to protect the delicate edges from oxidation when in contact with the air. Fill the space between the sides of the die and the box with the bone and charcoal mixture, and cover over with a thick layer of wet clay paste to prevent the charcoal from burning out. Dies made of steel having less than 60-point carbon content should always be carburized. Open-hearth steel dies containing 60-point carbon or over can be hardened without carburizing.

Heating the Die.—An oil or gas furnace is recommended for heating, although a coal or coke-fired muffle furnace, capable of maintaining a temperature of at least 1600 degrees F., may be used, provided the temperature can be held constant. A temperature indicating device is necessary. The die should be put into the furnace as soon as the latter is lighted. If the correct quenching temperature for the steel is, say, 1500 degrees F., the furnace should be checked when the pyrometer indicates 1400 degrees, the die being allowed to “soak” at that heat for three or four hours. Then the heat should be slowly raised to 1500 degrees and held at that point one or two hours longer, according to the size of the die. Five hours is the minimum total time for heating, and seven or eight hours is much safer. A 60-point carbon die should be quenched between 1425 and 1450 degrees F.

Cooling the Heated Die.—When cooling, the face of the die should receive a sufficient flow of cold water to cause it to harden to the greatest possible depth. The back of the die should, at the same time, be cooled to make the shrinkage of the face and back equal, and to prevent warping. A good form of cooling tank is one having a large supply pipe extending up through the bottom for cooling the die face, and a smaller pipe above the tank to cool the back. Unless a jet of water under pressure is applied to the face of the die, the sunken parts of the impression will not harden equally with the face. Dies should not be cooled in a tank of still water, because steam forms in the die cavity which prevents the water from enter-

ing, thus causing the formation of soft spots. To overcome this, the water must be forced into the impression by pressure sufficient to overcome the resistance of the steam thus formed. Oil should not be used for hardening hammer dies, as its cooling action is not great enough to produce a sufficient depth of hardening. Hammer dies which are simply surface hardened will not withstand the heavy blows received in service. To secure a greater hardening effect, brine of about 40 per cent solution is used by some die-makers.

Tempering Dies.—Dies should be tempered and drawn as soon as they are cool enough to remove from the tank. The dies should be heated in an oil bath, and quenched in water or cool oil. Any high-grade cylinder oil of high flash-point is suitable. Low-grade oils smoke unpleasantly and will not stand high temperatures. The drawing temperature of die steels is about 450 degrees F., for average conditions. The corners of the die and the cut-off should be drawn to a purple color with the aid of a blow torch.

Dies for Bronze and Copper Forgings.—Dies for producing drop-forgings from bronze or copper differ from those used for steel or iron forgings principally in the matter of finish. Owing to the softness of copper and bronze, the metal is driven into very minute impressions in the surface of the dies; hence, these surfaces must be perfectly free from scratches, in order to insure a smooth finish on the work. Even though these metals are soft, the hammering necessary when forging is very hard on the dies, and to prevent them from dishing or spreading, tool steel is ordinarily used, unless the forgings are extra large and heavy. The shrinkage, draft and finish allowances on this class of drop-forging dies are practically the same as on dies for steel and iron.

Trimming Dies for Drop-forgings.—Hot-trimming dies are made of a special grade of steel known as hot-trimming die-stock. The objection to use ordinary tool steel for hot-trimming dies is that the edges of a hardened die check badly after the die has been used for a short time, and this checking is followed by a breaking away of the steel around the edges, thus rendering the die unfit for use. This special steel requires no hardening, and after the die is in use, the edges toughen and give better service than the best hardened tool steel. The usual form of punch for hot-trimming dies merely supports the forging while it is being pushed through. If the forging has a broad, flat top face, the punch need only be a little more than a flat piece that covers the forging and acts as a pusher. Such punches are commonly made of cast iron. Cold-trimming dies are made from good tool steel of from 1.00 to 1.25 per cent carbon, and hardened and drawn to a dark straw color. The punches for cold trimmers are also made of tool steel and are hardened and drawn to a very dark straw color. These punches are hardened to prevent them from upsetting at the edges. As with hot-trimming punches, the punch should fit the die loosely, but it should support the forging at every point while it is being pushed through the die. There are two instances in which trimming punches should fit the dies as closely as the average punching die for sheet metal work; first, when trimming forgings on which the fin comes at the corner of the forging; second, forgings that are formed all in one die, the other die being flat. In these two cases, unless the dies fit very well, there will be burrs at the trimmed edges.

Standard Tolerances for Forgings.—The tolerances adopted by the Drop Forging Association in 1937 (see accompanying [Tables 69](#) through [73](#)) apply to forgings under 100 pounds each. Forging tolerances may either be "special" or "regular." *Special tolerances* are those which are particularly noted in the specifications and may state any or all tolerances in any way as required. Special tolerances apply only to the particular dimensions noted. In all cases where special tolerances are not specified, regular tolerances apply.

**Table 69. Standard Tolerances for Forgings Adopted, 1937,
by Drop Forging Association for Forgings under 100 Pounds Each**

Thickness Tolerances, Inch ^a									
Net Weights, Pounds, up to –	Commercial		Close		Net Weights, Pounds, up to –	Commercial		Close	
	–	+	–	+		–	+	–	+
.2	.008	.024	.004	.012	20	.026	.078	.013	.039
.4	.009	.027	.005	.015	30	.030	.090	.015	.045
.6	.010	.030	.005	.015	40	.034	.102	.017	.051
.8	.011	.033	.006	.018	50	.038	.114	.019	.057
1	.012	.036	.006	.018	60	.042	.126	.021	.063
2	.015	.045	.008	.024	70	.046	.138	.023	.069
3	.017	.051	.009	.027	80	.050	.150	.025	.075
4	.018	.054	.009	.027	90	.054	.162	.027	.081
5	.019	.057	.010	.030	100	.058	.174	.029	.087
10	.022	.066	.011	.033					

^a Thickness tolerances apply to the over-all thickness. For drop-hammer forgings, they apply to the thickness in a direction perpendicular to the main or fundamental parting plane of the die. For upset forgings, they apply to the thickness in the direction parallel to the travel of the ram, but only to such dimensions as are enclosed by the actually formed by the die.

**Table 70. Standard Tolerances for Forgings Adopted, 1937,
by Drop Forging Association for Forgings under 100 Pounds Each**

Shrinkage		Plus		Die Wear		Mismatching		
Lengths or widths up to – in.	Com- mercial + or –	Close + or –	Net wt. up to – lbs.	Com- mercial + or –	Close + or –	Net Weights, Pounds, up to –	Com- mercial	Close
1	.003	.002	1	.032	.016	1	.015	.010
2	.006	.003	3	.035	.018	7	.018	.012
3	.009	.005	5	.038	.019	13	.021	.014
4	.012	.006	7	.041	.021	19	.024	.016
5	.015	.008	9	.044	.022	25	.027	.018
6	.018	.009	11	.047	.024	31	.030	.020

For each additional inch under shrinkage, add 0.003 to the commercial tolerance and 0.0015 to the close tolerance. For example, if length or width is 12 inches, the commercial tolerance is plus or minus 0.036 and the close tolerance plus or minus 0.018.

For each additional 2 pounds under die wear, add 0.003 to the commercial tolerance and 0.0015 to the close tolerance. Thus, if the net weight is 21 pounds, the die wear commercial tolerance is 0.062 plus or minus, and the close tolerance 0.031 plus or minus.

For each additional 6 pounds under mismatching, add 0.003 to the commercial tolerance and 0.002 to the close tolerance. Thus, if the net weight is 37 pounds, the mismatching commercial tolerance is 0.033 and the close tolerance 0.022.

1	$\frac{1}{8}$	$\frac{1}{16}$	30	$\frac{7}{32}$	$\frac{7}{64}$
3	$\frac{5}{32}$	$\frac{5}{64}$	100	$\frac{1}{4}$	$\frac{1}{8}$

Regular tolerances: are divided into two divisions — “Commercial Standard” and “Close Standard.” “Commercial Standard” tolerances are for general forging practice, but when extra close work is desired involving additional expense and care in the production of forgings, “Close Standard” may be specified. When no standard is specified, “Commercial Standard” shall apply.

Regular tolerances are applicable to 1) thickness; 2) width, including shrinkage and die wear, mismatching, and trimmed size; 3) draft angle; 4) quantity in shipment; and 5) fillets and corners.

Thickness Tolerances: Thickness tolerances shall apply to the overall thickness of a forging. (See [Table 69](#).)

Width and Length Tolerances: Width and length tolerances shall be alike and shall apply to the width or length of a forging. When applied to drop hammer forgings, they shall apply to the width or length in a direction parallel to the main or fundamental parting plane of the die, but only to such dimensions as are enclosed by and actually formed by the die. When applied to upset forgings, they shall apply to the width or length in a direction perpendicular to the direction of travel of the ramp.

Width and length tolerances consist of the three subdivisions following: a) Shrinkage and die wear tolerance; b) mismatching tolerance; and c) trimmed size tolerance.

Welding Methods

Classes of Welds.—Welds are classified according to the way the ends are formed prior to making the weld. The different welds ordinarily made in hand forging practice are the scarf weld, butt weld, lap weld, cleft or split weld and jump weld. These welds are shown by the accompanying illustration. It will be seen that the surfaces, in most instances, are rounded or crowned. This is done so that when the heated ends are brought together they will unite first in the center. Any slag or dirt which may have adhered to the heated surfaces will then be forced out as the welding proceeds from the center outward. When making a lap weld, the hammering should begin at the center in order to work all the slag out, as the faces in this case are not rounded.

Welding Heat.—When two pieces of wrought iron or mild steel are heated until they become soft and plastic and will stick together when one is pressed or hammered against the other, they have reached what is commonly known as a welding heat. The quality of the weld depends largely upon the welding heat. If the ends to be heated are not hot enough, they will not stick together; inversely, if the work remains in the fire too long, it becomes overheated and burned, which greatly injures the metal. Iron which has been overheated has a rough, spongy appearance and is brittle. The danger of burning is increased when the air blast is too strong and the fire is oxidizing. It is important to heat the work slowly to secure a uniform temperature throughout the ends to be heated. With rapid heating, the outside may be raised to the welding temperature, while the interior is much below it; consequently, the weld will be defective.

Fire for Welding.—When heated iron comes into contact with the air it absorbs oxygen, thus forming a scale or oxide of iron on the surface, which prevents the formation of a good weld. A fire for heating parts to be welded should have a fairly thick bed between the tuyere and the work, so that the oxygen in the air blast will be consumed before it reaches the parts being heated. When there is only a thin bed of fuel beneath the work, or if too strong a blast is used, the excess of oxygen will pass through and oxidize the iron. The hotter the iron, the greater the formation of scale. The surface being heated can be given an additional protection by covering it with some substance that will exclude the air. (See "Fluxes for Welding.") Ordinarily, the air blast for a forge fire should have a pressure varying from 3 to 6 ounces per square inch. (See "Air Pressures and Pipe Sizes for Forges.")

Fluxes for Welding.—When iron is being heated preparatory to welding, the heated surfaces are oxidized to some extent or covered with oxide of iron, which forms a black scale when the hot iron comes into contact with the air. If this scale is not removed, it will cause a defective weld. Wrought iron can be heated to a high enough temperature to melt this oxide so that the latter is forced out from between the surfaces by the hammer blows; but when welding machine steel, and especially tool steel, a temperature high enough to melt the oxide would burn the steel, and it is necessary to use what is called a flux. This is a substance, such as sand or borax, having a melting temperature below the welding temperature of the work, and it is sprinkled upon the heated ends when they have reached about a yellow heat. The flux serves two purposes: It melts and covers the heated surfaces, thus protecting them from oxidation, and, when molten, aids in dissolving any oxide that may have formed, the oxide melting at a lower temperature when combined with the flux. Wrought

iron can be welded in a clean, well-kept fire without using a flux of any kind, except when the material is very thin. The fluxes commonly used are fine clean sand and borax. When borax is used, it will give better results if burned. This can be done by heating it in a crucible until reduced to the liquid state. It should then be poured onto a flat surface to form a sheet; when cold, it can easily be broken up and pulverized. The borax powder can be used plain or it can be mixed with an equal quantity of fine clean sand and about 25 per cent iron (not steel) filings. For tool steel, a flux made of one part sal-ammoniac and twelve parts borax is recommended. When pieces are put together previous to welding, as in split welds, or when taking a second heat (usually termed a "wash"), a flux that will flow easily should be used. There are many welding compounds on the market, some of which are suited for one class of welding and some for another.

Fuels for Forge.—Coke, coal, charcoal, oil and gas are used as fuels for heating iron and steel preparatory to forging or welding. For general work, a coke fire is the best, although bituminous coal is extensively used. With anthracite coal, it is difficult to get a hot enough fire, especially on a small forge. Coke or bituminous coal should be low in sulphur, because sulphur makes the iron "hot short" or brittle while hot. Sulphur, lead, bronze or brass must not be in the fuel or fire to be used for heating iron or steel. A weld may be spoiled by throwing brass filings into a fire before heating the work.

Machine Welding.—There are three common types of welds that can be made satisfactorily in a forging machine, simple examples of which are shown in the accompanying illustration.

Lap-welding: This is one of the most successful methods that can be used in joining pieces together in a forging machine, whenever requirements will permit. There are several applications of this type of welding: Two pieces can be joined together (as shown in the illustration) or several pieces can be welded together in one block. Machine lap-welding is also employed for enlarging the diameter of a bar, this being accomplished by welding a U-shaped piece of rectangular stock to the end, and then upsetting the mass into the shape desired. An end plunger is used to upset the bar after the latter is securely held between the opposing faces of the gripping dies.

Pin-welding: In order to make a pin weld, the end of the bar is reduced and inserted in a hole in the part to which it is to be joined (see illustration). The reduced end is usually made from one-quarter to one-half the diameter of the original bar. The U-shaped piece, or other part which is to be joined to it, is generally made thicker where the weld is made, in order to strengthen the weld. The welding operation is effected by a plunger in the ram of the machine, which upsets the "pin" and at the same time forms the joint.

Butt-welding: This method of machine welding is not as common as the other two methods referred to, but is satisfactory when properly applied. To make a butt weld, it is not necessary to prepare the stock beforehand, although the pieces should have practically the desired shape. The weld is effected by a plunger having a pointed end which is forced through the forward member to be joined, thus closely pressing together the material and insuring a solid weld (see illustration).

This method of welding is not considered as practicable as pin-welding, but when properly handled, it is satisfactory for many classes of work. Wrought iron is welded in a forging machine without using any flux but the parts to be joined must be clean and free from scale. As a rule, compressed air is used to remove the scale formed by oxidization. A small jet of air is directed against the work just before the machine is operated. For welding steel having a comparatively high carbon content, it is necessary to use a flux to make a satisfactory weld. (See "Fluxes for Welding.")

Hydraulic Press

Rules and Formulas for Hydraulic Press Calculations.—To find the total pressure of a hydraulic press when the diameter of the ram in inches and the water pressure (gage pressure) in pounds per square inch are given, multiply the area of the cross-section of the ram by the pressure per square inch, and divide by 2000. The result is the capacity of the hydraulic press in tons. The same result may be obtained as follows: Multiply the square of the diameter of the ram by the pressure per square inch, and multiply this product by 0.00039. The result is the total pressure of the press in tons.

The pressure per square inch on the material under pressure in the press can be determined when the total pressure of the press and the area of the material under pressure are known. Multiply the total pressure of the press in tons by 2000, and divide the product by the area of the material to be pressed. The quotient is the pressure in pounds per square inch on the surface of the material.

Table 74. Capacity of Hydraulic Presses

Diam. of Ram, Inches	Area of Ram, Sq. Ins.	Pressure in Pounds per Square Inch on End of Ram										
		2000	2100	2200	2300	2400	2500	2600	2700	2800	2900	3000

When a certain pressure per square inch on the material under pressure is required, the gage pressure of the press necessary to obtain this pressure may be calculated as follows: Multiply the area of the surface under pressure by the pressure per square inch desired on the material. Divide this product by 0.7854 times the square of the diameter of the ram. The quotient will be the desired gage pressure.

Expressing these rules as formulas, let D = diameter of ram in inches; P = water pressure in pounds per square inch (gage pressure); C = total pressure or capacity of press in tons; A = area of material to be pressed, in square inches; P_a = pressure in pounds per square inch on material under pressure; then:

$$C = 0.00039D^2 \times P \quad P_a = \frac{2000C}{A} \quad P = \frac{A \times P_a}{0.7854D^2}$$

SILENT OR INVERTED TOOTH CHAIN

Silent or inverted tooth chain consists of a series of toothed links alternately assembled either with pins or with a combination of joint components in such a way that the joints articulate between adjoining pitches. Side Guide chain has guide links which straddle the sprocket sides to control the chain laterally. Center Guide chain has guide links that run within a circumferential groove or grooves for lateral control.

Characteristics of Silent Chain Drives

The silent or "inverted-tooth" driving chain has the following characteristics: The chain passes over the face of the wheel like a belt and the wheel teeth do not project through it; the chain engages the wheel by means of teeth extending across the full width of the under side, with the exception of those chains having a central guide link; the chain teeth and wheel teeth are of such a shape that as the chain pitch increases through wear at the joints, the chain shifts outward upon the teeth, thus engaging the wheel on a pitch circle of increasing diameter; the result of this action is that the pitch of the wheel teeth increases at the same rate as the chain pitch. The accompanying illustration shows an unworn chain to the left, and a worn chain to the right, which has moved outward as the result of wear. Another distinguishing feature of the silent chain is that the power is transmitted by and to all the teeth in the arc of contact, irrespective of the increasing pitch due to elongation. The links have no sliding action either on or off the teeth, which results in a smooth and practically noiseless action, the chain being originally designed for the transmission of power at higher speeds than are suitable for roller chains. The efficiency of the silent chain itself may be as high as 99 per cent, and for the complete drive, from 96 to 97 percent, under favorable conditions; from 94 to 96 per cent can be secured with well-designed drives under average conditions.

The life and upkeep of silent chains depend largely upon the design of the entire drive, including the provision for adjustment. If there is much slack, the whipping of the chain will greatly increase the wear, and means of adjustment may double the life of the chain. A slight amount of play is necessary for satisfactory operation. The minimum amount of sag should be about $\frac{1}{8}$ inch. Although the silent chain shifts outward from the teeth and adjusts itself for an increase of pitch, it cannot take up the increased pitch in that portion of the chain between the wheels; therefore, the wheel must lag to the extent of the increased pitch in the straight portion of the chain.

Standard Silent Chain Designation.—The standard chain number or designation for $\frac{3}{8}$ -inch pitch or larger consists of:

1) a two letter symbol SC; 2) one or two numerical digits indicating the pitch in eighths of an inch; and 3) two or three numerical digits indicating the chain width in quarter-inches.

Thus, SC302 designates a silent chain of $\frac{3}{8}$ -inch pitch and $\frac{1}{2}$ -inch width, while SC1012 designates a silent chain of $1\frac{1}{4}$ -inch pitch and 3-inch width.

The standard chain number or designation for $\frac{3}{16}$ -inch pitch consists of:

a) a two letter symbol SC; b) a zero followed by a numerical digit indicating pitch in sixteenths of an inch; and c) two numerical digits indicating the chain width in thirty-seconds of an inch. Thus, SC0309 designates a silent chain of $\frac{3}{16}$ -inch pitch and $\frac{9}{32}$ -inch width.

Silent Chain Links.—The joint components and link contours vary with each manufacturer's design. As shown in [Table 1](#) minimum crotch height and pitch have been standardized for interchangeability. Chain link designations for $\frac{3}{8}$ -inch and larger pitch are given in [Table 1](#)

Table 1. American National Standard Silent Chain Links*

Chain Number	Chain Pitch		Stamp	Crotch Height, Min.	
	inch	mm		inch	mm
SC3 (Width in $\frac{1}{4}$ in.)	0.375	9.52	SC3 or 3	0.0232	0.589
SC4 (Width in $\frac{1}{4}$ in.)	0.500	12.70	SC4 or 4	0.0310	0.787
SC5 (Width in $\frac{1}{4}$ in.)	0.625	15.88	SC5 or 5	0.0388	0.985
SC6 (Width in $\frac{1}{4}$ in.)	0.750	19.05	SC6 or 6	0.0465	1.181
SC8 (Width in $\frac{1}{4}$ in.)	1.000	25.40	SC8 or 8	0.0620	1.574
SC10 (Width in $\frac{1}{4}$ in.)	1.250	31.76	SC10 or 10	0.0775	1.968
SC12 (Width in $\frac{1}{4}$ in.)	1.500	38.10	SC12 or 12	0.0930	2.302
SC16 (Width in $\frac{1}{4}$ in.)	2.000	50.80	SC16 or 16	0.1240	3.149

Min. Crotch Height = $0.062 \times \text{Chain Pitch}$.

Link contour may vary but must engage standard sprocket tooth so that joint centers lie on pitch diameter of sprockets.

Silent Chain Sprocket Diameters.—The important sprocket diameters are:

- 1) outside diameter; 2) pitch diameter; 3) maximum guide groove diameter; and
- 4) over-pin diameter.

These are shown in the diagram in [Table 2](#) and the symbols and formulas for each are also given in this table. [Table 3a](#) gives values of outside diameters for sprockets with rounded teeth and with square teeth, pitch diameters, and over-pin diameters for chains of 1-inch pitch and sprockets of various tooth numbers. Values for chains of other pitches ($\frac{3}{8}$ inch and larger) are found by multiplying the values shown by the pitch. [Table 3b](#) gives this information for $\frac{3}{16}$ -in. pitch chains. Note that the over-pin diameter is measured over gage pins having a diameter $D_p = 0.625P$ in. for $\frac{3}{8}$ -in. and larger pitch and $D_p = 0.667P$ in. for $\frac{3}{16}$ -in. pitch chains. Over-pin diameter tolerances are given in [Table 4a](#) and [4b](#).

Silent Chain Sprocket Profiles and Chain Widths.—Sprocket tooth face profiles for side guide chain, center guide chain and double guide chain are shown in [Table 4c](#) and [4d](#) together with important dimensions for chains of various pitches and widths. Maximum over-all width M of the three types of chain are also given in this table for various pitches and widths. It should be noted that the sprocket tooth width W for the side guide chain is given in [Table 5](#) for one-half-inch wide chains of $\frac{3}{8}$ -inch and $\frac{1}{2}$ -inch pitches. No values of W for other chain sizes are specified in American National Standard B29.2M-1982 (1987).

* For $\frac{3}{8}$ -inch and larger pitch chains.

Table 2. ANSI Silent Chain Sprocket Diameters (ANSI B29.2M-1982, R1987)

P = Chain Pitch
 PD = Pitch Diameter
 OD = Outside Diameter
 D_p = Gage Pin Diameter
 N = Number of Teeth
 E = Diameter to center of Topping Curve
 OPD = Over Pin Diameter
 G = Max. Guide Groove Diameter

$$PD = \frac{P}{\sin \frac{180^\circ}{N}}$$

$D_p = 0.625P$, for $\frac{3}{8}$ in. and larger pitch chain
 [= 0.667P for $\frac{3}{16}$ in. pitch chain]

$$OPD \text{ (For Even No. of Teeth)} = PD - 0.125P \csc \left(30 - \frac{180^\circ}{N} \right) + 0.625P$$

$$\left[= PD - 0.160P \csc \left(30 - \frac{180^\circ}{N} \right) + 0.667P \right]$$

$$OPD \text{ (For Odd No. of Teeth)} = \cos \frac{90^\circ}{N} \left[PD - 0.125P \csc \left(30 - \frac{180^\circ}{N} \right) \right] + 0.625P$$

$$\left[= \cos \frac{90^\circ}{N} \left[PD - 0.160P \csc \left(30 - \frac{180^\circ}{N} \right) \right] + 0.625P \right]$$

$$OD \text{ (For Round Teeth)} = P \left(\cot \frac{180^\circ}{N} + 0.08 \right)$$

$$\left[OD \text{ (For Nominal Round Teeth)} = P \left(\cot \frac{180^\circ}{N} - 0.032 \right) \right]$$

$$OD \text{ (For Square Teeth)} = 2\sqrt{X^2 + L^2} - 2XL \cos \alpha$$

Where

$$X = Y \cos \alpha - \sqrt{(0.15P)^2 - (Y \sin \alpha)^2}$$

$$Y = P(0.500 - 0.375 \sec \alpha) \cot \alpha + 0.11P$$

$$L = Y + \frac{E}{2} \text{ (See Table 8A for E);}$$

$$\alpha = \left(30 - \frac{360^\circ}{N} \right)^\circ$$

$$G(\text{max.}) = P \left(\cot \frac{180^\circ}{N} - 1.16 \right)$$

$$\left[G(\text{max.}) = P \left(\cot \frac{180^\circ}{N} - 1.20 \right) \right]$$

Tolerance = +0, -0.030 in. (0.76 mm)

[Tolerance = +0, -0.015 in. (0.38 mm)]^a

^a All inside [] bracket applies to $\frac{3}{16}$ -inch pitch main. All other equations apply to $\frac{3}{8}$ -inch and larger pitch chains.

**Table 3a. American National Standard Silent Chain
Sprocket Diameters ANSI B29.2M-1982, R1987**

These diameters apply only to chain of 1-inch pitch. For any other pitch ($\frac{3}{8}$ -inch and larger) multiply the values given below by the pitch.

SILENT OF INVERTED TOOTH CHAIN

Table 3a. (Continued) American National Standard Silent Chain Sprocket Diameters ANSI B29.2M-1982, R1987

These diameters apply only to chain of 1-inch pitch. For any other pitch ($\frac{3}{8}$ -inch and larger) multiply the values given below by the pitch.									
No. Teeth	Pitch Diameter	Outside Diameter		Over Pin Diameter ^a	No. Teeth	Pitch Diameter	Outside Diameter		Over Pin Diameter
		Rounded Teeth ^b	Square Teeth ^c				Rounded Teeth	Square Teeth	
96	30.563	30.627	30.591	30.923	125	39.793	39.860	39.830	40.153

107	6.387	6.378	6.457	6.159	120	7.163	7.154	7.233	6.935

^aFor tolerances on over-pin diameters, see table 4.

^bBlank diameters are 0.020 inch larger and maximum guide groove diameters G are 1.240 inches smaller than these outside diameters.

^cThese diameters are maximum; tolerance is +0, -0.50 × pitch, inches.

Tolerance for maximum eccentricity (total indicator reading) of pitch diameter with respect to bore is 0.004 in. up to and including 4 in. diameter; and 0.008 in., over 4 in. diameter.

Table 4a. Over-Pin Diameter Tolerances for American National Standard $\frac{3}{8}$ -in. Pitch and Larger Silent Chain Sprocket Measurement ANSI B29.2M-1982, 1987

4.76	0.10	0.10	0.10	0.10	0.10	0.13	0.13	0.13	0.13	0.13

^aAll tolerances are negative.

Grooving tool may be either square or round end but groove must be full width down to diameter of G . For values of G (max.) see footnote to Table 3a

Values of H (± 0.003 in.) = 0.051 in. are given only for chain numbers SC302 and SC402. M = Max. overall width of chain. The maximum radius over a new chain engaged on a sprocket will not exceed the sprocket pitch radius plus 75 per cent of the chain pitch. To obtain the chain widths and sprocket face dimensions in millimeters, multiply each entry by 25.4.

All dimensions in inches. M = Max. overall width of chain.

To obtain chain width and sprocket face dimensions in millimeters, multiply each entry by 25.4.

Sprocket Hub Dimensions.—The important hub dimensions are the outside diameter, the bore, and the length. The maximum hub diameter is limited by the need to clear the chain guides and is of particular importance for sprockets with low numbers of teeth. The American National Standard for inverted tooth chains and sprocket teeth ANSI B29.2M-1982 (R1987) provides the following formulas for calculating maximum hub diameters, *MHD*.

$$MHD(\text{for hobbled teeth}) = P \left[\cot \left(\frac{180^\circ}{N} \right) - 1.33 \right]$$

$$MHD(\text{for straddle cut teeth}) = P \left[\cot \left(\frac{180^\circ}{N} \right) - 1.25 \right]$$

Maximum hub diameters for sprockets with from 17 to 31 teeth are given in Table 5. Maximum hub diameters for other methods of cutting teeth may differ from these values. Recommended maximum bores are given in Table 6.

Table 5. American National Standard Minimum Hub Diameters for Silent chain Sprockets (17 to 31 Teeth) ANSI B29.2M-1982, 1987

No. Teeth	Hob cut	Straddle Cut	No. Teeth	Hob cut	Straddle Cut	No. Teeth	Hob cut	Straddle Cut
	Min. Hub Diam.			Min. Hub Diam.			Min. Hub Diam.	
17	4.019	4.099	22	5.626	5.706	27	7.226	7.306
18	4.341	4.421	23	5.946	6.026	28	7.546	7.626
19	4.662	4.742	24	6.265	6.345	29	7.865	7.945
20	4.983	5.063	25	6.586	6.666	30	8.185	8.265
21	5.304	5.384	26	6.905	6.985	31	8.503	8.583

All dimensions in inches.

Values shown are 1-inch pitch chain. For other pitches ($\frac{3}{8}$ -inch and larger) multiply the values given by the pitch.

Good practice indicates that teeth of sprockets up to and including 31 teeth should have a Rockwell hardness of C50 min.

^b Suggested standard. Bores other than standard must be specified.

All dimensions in inches. To obtain values in millimeters, multiply inch values by 25.4. These data are given as supplementary information in ANSI B29.2M-1982, R1987 and are made available by the American Chain Association.

Fig. 3. Identification of Inverted Tooth Chain Hobs.

Table 9. Hobs for ANSI $\frac{3}{8}$ -inch and larger Silent Tooth Sprocket*

P = Chain Pitch

N = Number of Teeth

$$HGD = P \sqrt{\frac{1}{\sin \frac{180^\circ}{N}} + 0.5625 - \frac{1.5 \sin \left(30 - \frac{180^\circ}{N} \right)}{\sin \frac{180^\circ}{N}}}$$

Sprocket Design and Tooth Form.—Except for tooth form, silent chain sprocket design parallels the general design practice of roller chain sprockets as covered in the previous section.

As shown in Tables 7a and 7b, sprockets for American National Standard silent chains have teeth with straight-line working faces. The tops of teeth for $\frac{3}{8}$ -in. and larger pitch chains may be rounded or square. Bottom clearance below the working face is not specified but must be sufficient to clear the chain teeth. The standard tooth form for $\frac{3}{8}$ -in. and larger pitch chains is designed to mesh with link plate contours having an included angle of 60 degrees as shown in the diagram of Table 7a. The standard tooth form for $\frac{3}{16}$ -in. pitch chains has an included angle of 70 degrees as shown in Table 7b. It will be seen from these tables that the angle between the faces of a given tooth [$60^\circ - 720^\circ/N$ for $\frac{3}{8}$ -in. pitch and larger; $70^\circ - 720^\circ/N$ for $\frac{3}{16}$ -in. pitch] becomes smaller as the number of teeth decreases. Therefore, for a $\frac{3}{8}$ -in. pitch or larger 12-tooth sprocket it will be zero. In other words the tooth faces will be parallel.

For smaller tooth numbers the teeth would be undercut. For best results, 21 or more teeth are recommended; less than 17 should not be used.

Cutting Silent Chain Sprocket Teeth.—Sprocket teeth may be cut by either a straddle cutter or a hob. Essential dimensions for straddle cutters are given in Table 8 and for hobs in Table 9 and 10. American National Standard silent chain hobs are stamped for identification as shown on page 2375.

Design of Silent Chain Drives.—The design of silent chain transmissions must be based not only upon the power to be transmitted and the ratio between driving and driven shafts, but also upon such factors as the speed of the faster running shaft, the available space, assuming that it affects the sprocket diameters, the character of the load and certain other factors. Determining the pitch of the chain and the number of teeth on the smallest sprocket are the important initial steps. Usually any one of several combinations of pitches and sprocket sizes may be employed for a given installation. In attempting to select the best combination, it is advisable to consult with the manufacturer of the chain to be used. Some of the more important fundamental points governing the design of silent chain transmissions will be summarized.

The design of a silent chain drive consists, primarily, of the selection of the chain size, sprockets, determination of chain length, center distance, lubrication method, and arrangement of casings.

Pitch of Silent Chain.—The pitch is selected with reference to the speed of the faster running shaft which ordinarily is the driver and holds the smaller sprocket. The following pitches are recommended: for a faster running shaft of 2000 to 5000 rpm, $\frac{3}{8}$ -inch pitch; for 1500 to 2000 rpm, $\frac{1}{2}$ -inch pitch; for 1200 to 1500 rpm, $\frac{5}{8}$ -inch pitch, for 1000 to 1200 rpm, $\frac{3}{4}$ -inch pitch; for 800 to 1000 rpm, 1-inch pitch; for 650 to 800 rpm, $1\frac{1}{4}$ -inch pitch; for 300 to 600 rpm, $1\frac{1}{2}$ -inch pitch; for 300 to 500 rpm, 2-inch pitch; and for below 300 rpm, $2\frac{1}{2}$ -inch pitch. As the normal operating speeds increase, the allowable pitch decreases. Recommendations relating to the relationship between pitch and operating speed are intended for normal or average conditions. Speeds for a given pitch may be exceeded under favorable conditions and may have to be reduced when conditions are unfavorable. In general, smoother or quieter operation will result from using the smallest pitch suitable for a given speed and load. However, a larger pitch which might be applicable under the same conditions, will result in a narrower chain and a less expensive transmission. This relationship usually is true when there is a small speed reduction and comparatively long center distance. If there is a large speed reduction and short center distance, drives having the smaller pitches may be less expensive.

Maximum Ratios for Silent Chain Drives.—The maximum permissible ratios between driving and driven sprockets vary somewhat for different conditions and usually range from 6- or 7-to-1 up to 10-to-1. Some drives have even higher ratios, especially when the operating conditions are exceptionally favorable. When a large speed reduction is necessary, it is preferable as a general rule to use a double reduction or compound type of transmission instead of obtaining the entire reduction with two sprockets. Drives should be so proportioned that the angle between the two strands of a tight chain does not exceed 45 degrees. When the angle is larger, the chain does not have sufficient contact with the driving sprocket.

Sprocket Size and Chain Speed: A driving sprocket with not less than 17 teeth is generally recommended. For the driven sprocket, one manufacturer recommends 127 teeth as a maximum limit and less than 100 as preferable. If practicable, the sprocket sizes should be small enough to limit the chain speed to from 1200 to 1400 feet per minute. If the chain speed exceeds these figures, this may indicate that the pitch is too large or that a smaller pitch, and, consequently, a reduction in sprocket diameters (and chain speed) will result in better operating conditions. Both sprockets should preferably have a "hunting tooth ratio" relative to the number of chain links for uniform wear. See "Hunting Tooth Ratios," page 1867.

If there is a small reduction in speed between the driving and driven shafts, both sprockets may be made as small as is consistent with satisfactory operation, either to obtain a compact drive or possibly to avoid excessive chain speed in cases where the rotative speed is high for a given horsepower. Under such conditions, one manufacturer recommends driving sprockets ranging from 17 to 30 teeth, and driven sprockets ranging from 19 to 33

teeth. If the number of revolutions per minute is low for a given horsepower and the center distance comparatively long, then the recommended range for driving sprockets is from 23 to iii teeth, and driven sprockets from 27 to 129 teeth. The preferable range is from 17 to 75 teeth for the driving sprockets, and 19 to 102 teeth for the driven sprockets.

Center Distance for Silent Chain Drives.—If the ratio of the drive is small, it is possible to locate the sprockets so close—that the teeth just clear; however, as a general rule, the minimum center-to-center distance should equal the sum of the diameters of both sprockets. According to the Whitney Chain & Mfg. Co., if the speed ratio is not over $2\frac{1}{2}$ -to-1, the center distance may be equal to one-half the sum of the sprocket diameters plus tooth clearance, providing this distance is not less than the minimum given in Table 11. If the speed ratio is greater than $2\frac{1}{2}$ -to-1, the center distance should not be less than the sum of the sprocket diameters.

Table 11. Minimum Center Distances for Various Pitches

Pitch, inches	$\frac{3}{8}$	$\frac{1}{2}$	$\frac{5}{8}$	$\frac{3}{4}$	1	$1\frac{1}{4}$	$1\frac{1}{2}$
Minimum Center Distances, inches	6	9	12	15	21	27	33

When the chain length in pitches is known, the equivalent center distance for a tight chain may be determined by the formula for roller chain found on page 2348.

In selecting chain length, factors determining length should be adjusted so that the use of offset links may be avoided wherever possible. Chain lengths of an uneven number of pitches are also to be avoided.

Silent Tooth Chain Horsepower Capacity.—The horsepower ratings given in Tables 12a, 12b, and 12c have been established on a life expectancy of approximately 15,000 hours under optimum drive conditions, i.e. for a uniform rate of work where there is relatively little shock or load variation throughout a single revolution of a driven sprocket. Using these horsepower ratings as a basis, engineering judgment should be exercised as to the severity of the operating conditions for the intended installation, taking into consideration the source of power, the nature of the load, and the resulting effects of inertia, strain, and shock. Thus, for other than optimum drive conditions, the specified horsepower must be multiplied by the applicable service factor to obtain a “design” horsepower value. This is the value used to enter Table 13 to obtain the required size of chain.

Service Factors: For a uniform type of load, a service factor of 1.0 for a 10-hour day and 1.3 for a 24-hour day are recommended. For a moderate shock load, service factors of 1.4 for a 10-hour day and 1.7 for a 24-hour day are recommended. For heavy shock loads, service factors of 1.7 for a 10-hour day and 2.0 for a 24-hour day are recommended. For extensive table of service factor applications, see supplementary information in ANSI B29.2M-1982.

Installation of Silent Chain Drives.—In installing chain transmissions of any kind, horizontal drives are those having driving and driven shafts in a horizontal plane. These are always preferable to vertical drives, which have a vertical center line intersecting the driving and driven shafts. If one sprocket must be higher than the other, avoid a vertical drive if possible by so locating the two sprockets that the common center line inclines from the vertical as far as is permitted by other conditions which might govern the installation. If practicable, an adjustment should be provided for the center distance between the driving and driven shafts.

Slack Side of Chain: As a general rule, the slack strand of a chain should be on the lower side of a horizontal drive. If the drive is not horizontal but angular or at some angle less than 90 degrees from the vertical, the slack should preferably be on that side which causes the strand to curve outward or away from the center line of the driving and driven shafts. Whenever the slack strand is on the upper side of either a horizontal or inclined drive,

adjustment for the center distance is especially important to compensate for possible chain elongation.

Lubrication: The life of a silent chain subjected to conditions such as are common to automobile drives, depends largely upon the wear of the joints. On account of the high speed and whipping action, it is important to have the chains well oiled. When splash lubrication is employed, the supply pipe should be placed so that the oil will be directed against the inside of the chain. It is preferable that silent chains be operated in an oil-retaining casing with provisions for lubrication. Avoid using greases of any kind. The viscosity of the oil depends on temperature, as follows:

Ambient Temp. °F	Chain Pitch		Ambient Temp. °F	Chain Pitch	
	$\frac{3}{16}$ & $\frac{3}{8}$ inch	$\frac{1}{2}$ inch & larger		$\frac{3}{16}$ & $\frac{3}{8}$ inch	$\frac{1}{2}$ inch & larger
	Recommended Lubricant			Recommended Lubricant	
20-40	SAE 10	SAE 20	20-40	SAE 10	SAE 20
40-100	SAE 20	SAE 30	40-100	SAE 20	SAE 30

Double-Flexure Silent Chain.—In double-flexure chain, the teeth of the link plates project on both sides of the chain and the chain flexes in both directions. This chain is used where the drive arrangements require that sprockets contact both sides of the chain. Neither double-flexure chain nor sprockets are covered in American National Standard ANSI B29.2M-1982.

Horsepower Ratings Per Inch of Chain Width for Silent Chain Drives — 1982.—

The following industrial standard horsepower ratings for silent chain drives have been supplied by the American Chain Association. These ratings are for American National Standard silent chain as covered by ANSI B29.2M-1982. These values may require modification by using the appropriate service factors (see page 2379). These factors, which apply to typical drives, are intended as a general guide only, and engineering judgment and experience may indicate different modifications to suit the nature of the load.

$$\text{Horsepower capacity of chain per inch of width} = \frac{\text{Rating in Table 12A, 12B}}{\text{Service Factor}}$$

$$\text{chainwidth for given total hp capacity} = \frac{\text{hp} \times \text{Service factor}}{\text{Rating per inch, Table 12A, 12B}}$$

Lubrication: The horsepower established from the sprocket and speed combinations of the drive under consideration will indicate a method of lubrication. This method or a better one must be used to obtain optimum chain life. The types of lubrication as indicated on the tables are: Type I, manual, brush, or oil cup; Type II, bath or disk; Type III, circulating pump.

GEARS AND GEARING

Geometry Factors For Gear Teeth

Contact and Bending Stresses.—To calculate the contact and bending stresses acting between the teeth of a pair of gears meshing under load, it is necessary to include in the stress formulas a number of factors that account for the geometry of the teeth, the physical properties of the materials used, and the nature of the specific application.

AGMA 908-B89 Information Sheet* gives equations for calculating the pitting resistance geometry factor, I , for external and internal spur and helical gears; and the bending strength geometry factor, J , for external spur and helical gears that are generated by rack-type tools (hobs, rack cutters, or generating grinding wheels) or pinion-type tools (shaper cutters). The document includes 66 tables of geometry factors, I and J , for a range of typical gear sets and tooth forms of $14\frac{1}{2}$ -, 20-, and 25-deg pressure angles and 0-, 10-, 15-, 20-, 25-, and 30-deg helix angles.

The Information sheet was prepared to assist designers making preliminary design studies and to present data useful to those without access to computer programs. Not all tooth forms, pressure angles, and pinion and gear modifications are covered. Neither are these data applicable to all gear designs; however, the data should be helpful to the majority of gear designers. Data from this Information Sheet are used with the rating procedures described in AGMA 2001-B88, *Fundamental Rating Factors and Calculation Methods for Involute Spur and Helical Gear Teeth*, for evaluating various spur and helical gear designs produced by using a generating process (see page 1834).

Geometry Factors for Pitting Resistance and Bending Strength.—The AGMA Information Sheet includes a mathematical procedure to determine the pitting resistance geometry factor, I , for internal and external gear sets of spur, conventional helical, and low-axial-contact-ratio (LACR) helical design. A mathematical procedure is also included to determine the bending strength geometry factor, J , for external gear sets of spur, conventional helical, and low-axial-contact-ratio (LACR) helical designs. The calculation procedure is valid for generated root fillets produced by both rack- and pinion-type tools.

Exceptions to the Information Sheet Data and Procedures.—The formulas in the Information Sheet are not valid when any of the following conditions exist:

1) Spur gears with transverse contact ratio less than one, $m_p < 1.0$; 2) spur or helical gears with transverse contact ratio equal or greater than two, $m_p \geq 2.0$; 3) interference exists between the tips of teeth and root fillets; 4) the teeth are pointed; 5) backlash is zero; 6) undercut exists in an area above the theoretical start of the active profile (the effect of this undercut is to move the highest point of single tooth contact, negating the assumption of this calculation method; however, the reduction in tooth thickness due to protuberance below the active profile is handled correctly by this method); 7) the root profiles are stepped or irregular (the J factor calculation uses the stress correction factors developed by Dolan and Broghamer; the factors may not be valid for root forms that are not smooth curves; for root profiles that are stepped or irregular, other stress correction factors may be appropriate); 8) where root fillets of the gear teeth are produced by a process other than generating; and 9) the helix angle at the standard (reference) diameter is greater than 50 deg.

In addition to these exceptions, it is assumed that 1) the friction effect on the direction of force is neglected; and 2) the fillet radius is smooth (it is actually a series of scallops).

Basic Gear Geometry of Spur and Helical Gears.—The equations that follow apply to spur and helical gears. Where double signs are used (e.g., \pm), the upper sign applies to exter-

* Extracted from AGMA 908-B89, Information Sheet, *Geometry Factors for Determining the Pitting Resistance and Bending Strength of Spur, Helical, and Herringbone Gear Teeth*, with the permission of the publisher, American Gear Manufacturers Association, 1500 King Street, Suite 201, Alexandria, Virginia 22314.

nal gears and the lower sign to internal gears. The equations given are based on unity normal module ($m_n = 1$) or unity normal diametral pitch ($P_{nd} = 1$) and are valid for any consistent set of units. All angles are in radians unless otherwise specified. *In using the given equations, certain variables must be made dimensionless by dividing by the normal module m_n or multiplying by the normal diametral pitch P_{nd} .* For example, if a face width F 0.5 in. and the normal diametral pitch is 4, then the value of F to be used in the equations is $0.5 \times 4 = 2$. The variables to be so adjusted are $F, R_{o1}, R_{o2}, R_{oc}, R_c, h_{ao}, \delta_{ao}, \rho_{ao},$ and Δ_{sn} .

$$\text{Gear ratio, } m_G = \frac{n_2}{n_1}, \text{ Where } n_1 \text{ and } n_2 \text{ are pinion and gear tooth numbers} \quad (1)$$

$$\text{Standard (reference) pinion pitch radius, } R_1 = \frac{n_1}{2 \cos \psi} \quad (2)$$

Where ψ = standard helix angle.

$$\text{Standard (reference) gear pitch radius, } R_2 = R_1 m_G \quad (3)$$

$$\text{Standard transverse pressure angle, } \phi = \arctan\left(\frac{\tan \phi_n}{\cos \psi}\right) \quad (4)$$

Where ϕ_n = standard normal pressure angle.

$$\text{Pinion base radius, } R_{b1} = R_1 \cos \phi \quad (5)$$

$$\text{Gear base radius, } R_{b2} = R_{b1} m_G \quad (6)$$

$$\text{Operating transverse pressure angle, } \phi_r = \arccos\left(\frac{R_{b2} \pm R_{b1}}{C_r}\right) \quad (7)$$

Where C_r = Operating center distance.

$$\text{Transverse base pitch, } P_b = \frac{2\pi R_{b1}}{n_1} \quad (8)$$

$$\text{Normal base pitch, } P_N = \pi \cos \phi_n \quad (9)$$

$$\text{Base helix angle, } \psi_b = \arccos\left(\frac{P_N}{P_b}\right) \quad (10)$$

Fig. 1 shows a view of the line of action in the transverse plane of two meshing gears. The distances C_1 , through C_6 are derived from this figure taking into account the exceptions noted previously with regard to undercut.

$$C_6 = C_r \sin \phi_r \quad (11)$$

$$C_1 = \pm [C_6 - (R_{o2}^2 - R_{b2}^2)^{0.5}] \quad (12)$$

where R_{o2} = addendum radius of gear, for internal or external gears.

$$C_3 = \frac{C_6}{(m_G \pm 1)} \quad (13)$$

$$C_4 = C_1 + P_b \quad (14)$$

$$C_5 = (R_{o1}^2 - R_{b1}^2)^{0.50} \tag{15}$$

Where R_{o1} = addendum radius of pinion.

$$C_2 = C_5 - P_b \tag{16}$$

$$\text{Active length of line of contact, } Z = C_5 - C_1 \tag{17}$$

Distance C_2 locates the lowest point of single tooth contact (LPSTC); distance C_4 locates the highest point of single tooth contact (HPSTC), where C_r , R_{o1} , and R_{o2} are values for $m_n = 1$ or $P_{nd} = 1$.

Fig. 1. Transverse Plane View of the Line of Action

Contact Ratios.—The contact ratios are as follows:

$$\text{Transverse Contact ratio, } m_p = \frac{Z}{P_b} \tag{18}$$

$$\text{Axial pitch, } P_x = \frac{\pi}{\sin \psi} \tag{19}$$

$$\text{Axial contact ratio, } m_F = \frac{F}{P_x} \tag{20}$$

where F = effective face width at $m_n = 1$ or $P_{nd} = 1$. For spur gears, $m_F = 0$.

Minimum Lengths of Lines of Contact.—For spur gears with $m_p < 2.0$ the minimum length of contact lines, L_{min} ,

$$L_{min} = F \tag{21}$$

For helical gears, two cases must be considered:

$$\text{Case I: For } n_a \leq 1 - n_r, L_{min} = \frac{(m_p F - n_a n_r p_x)}{\cos \psi_b} \tag{22}$$

$$\text{Case II: For } n_a > 1 - n_r, L_{min} = \frac{[m_p F - (1 - n_a)(1 - n_r)p_x]}{\cos \psi_b} \tag{23}$$

where n_r = fractional part of m_p , and n_a = fractional part of m_F . For example, if $m_p = 1.4$, then $n_r = 0.4$.

Load Sharing Ratio, m_N .—The load sharing ratio m_N is calculated as follows:

$$\text{For helical gears, } m_N = \frac{F}{L_{min}} \tag{24}$$

$$\text{For spur gears with } m_p \leq 2.0, \text{ Eq. (21) has } L_{min} = F \text{ so that } m_N = 1.0 \tag{25}$$

For low axial contact ratio (LACR) helicals, $m_F \leq 1.0$. Load sharing is accommodated by the helical overlap factor C_ψ [Equation (36)]; therefore,

$$m_N = 1.0 \tag{26}$$

$$\text{Operating helix angle, } \psi_r = \arctan\left(\frac{\tan \psi_b}{\cos \phi_r}\right) \tag{27}$$

$$\text{Operating normal pressure angle, } \phi_{nr} = \arcsin(\cos \psi_b \sin \phi_r) \tag{28}$$

Calculating the Pitting Resistance Geometry Factor, I .—The pitting resistance geometry factor I is a dimensionless number that takes into account the effects of the radii of curvature of the gear tooth surfaces, load sharing, and the normal component of the transmitted load:

$$I = \frac{\cos \phi_r C_\psi^2}{[(1/\rho_1 + 1/\rho_2)(dm_N)]} \tag{29}$$

where

ϕ_r = operating transverse pressure angle [Equation (7)];

C_ψ = helical overlap factor [Equation (36)];

d = pinion operating pitch diameter [Equation (30)];

m_N = load sharing ratio [Equation (24), (25), or (26)]; and

ρ_1 and ρ_2 = radii of curvature of pinion and gear profiles, respectively, at point of stress calculation.

$$\text{Operating pitch diameter of pinion, } d = \frac{2c_r}{(m_G + 1)} \tag{30}$$

Radii of Curvature of Profiles at Contact Stress Calculation Point: For conventional helical gears ($m_F > 1$) the radii of curvature are calculated at the mean radius or middle of the working profile of the pinion where

$$\text{Mean radius of pinion, } R_{m1} = \frac{1}{2}[R_{O1} \pm (C_r - R_{O2})] \quad (31)$$

where

R_{O1} = addendum radius of pinion and;

R_{O2} = addendum radius of gear, internal or external.

$$\text{radius of curvature of pinion profile, } \rho_1 = (R_{m1}^2 - R_{b1}^2)^{0.50} \quad (32)$$

Where R_{b1} = base radius of pinion.

$$\text{Radius of curvature of gear profile, } \rho_2 = C_6 \mp \rho_1 \quad (33)$$

For spurs and LACR helicals ($m_F \leq 1$), the radii of curvature are calculated at the LPSTC:

$$\rho_1 = C_2 \quad (34)$$

$$\rho_2 = C_6 \mp \rho_1 \quad (35)$$

Helical overlap factor for LACR ($m_F \leq 1$), helical gears,

$$C_\psi = \left[1 - m_F \left(1 - \frac{\rho_{m1} \rho_{m2} Z}{\rho_1 \rho_2 \rho_N} \right) \right]^{0.50} \quad (36)$$

where Z = Equation (17); ρ_N = Equation (9); ρ_{m1} = Equation (37) and, ρ_{m2} = Equation (38).
radius of curvature of pinion profile at mean radius of profile,

$$\rho_{m1} = (R_{m1}^2 - R_{b1}^2)^{0.50} \quad (37)$$

Radius of curvature of gear profile at mean radius of gear,

$$\rho_{m2} = C_6 \mp \rho_{m1} \quad (38)$$

$$\text{For spur and conventional helicals, } C_\psi = 1 \quad (39)$$

Bending Strength Geometry Factor, J .—The bending strength geometry factor is a dimensionless number that takes into account: 1) shape of the tooth; 2) worst load position; 3) stress concentration; and 4) load sharing between oblique lines of contact in helical gears.

Both tangential (bending) and radial (compressive) components of the tooth load are included. The equations and calculation procedures for the bending stress geometry factor are not given here, but may be found in AGMA 908-B89. The procedures apply only to external gears and must be repeated for both the pinion and the gear using the appropriate dimensions for each.

Generating Tool Geometry: Details of the methods for calculating the geometry of the tools used to generate tooth profiles are provided in the Information Sheet as part of the J -factor calculation procedure.

*Included in the AGMA Information Sheet are the equations needed to write a computer program to calculate values not given in the tables of J factors.

Fig. 2. Load Angle and Load Radius

Fig. 3. Pressure Angle Where Tooth Comes to Point

Virtual Spur Gear: Helical gears are considered to be virtual spur gears with the following virtual geometry:

$$\text{Virtual tooth number, } n = \frac{n_1}{\cos \psi^3} \tag{40}$$

$$\text{Standard (ref) pitch radius of virtual spur gear, } r_n = \frac{n}{2} \tag{41}$$

$$\text{Virtual base radius, } r_{nb} = r_n \cos \phi_n \tag{42}$$

$$\text{Virtual outside radius, } r_{na} = r_n + R_{01} - R_1 \tag{43}$$

For spur gears, the virtual geometry is the same as the actual geometry:

$$n = n_1 \tag{44}$$

$$r_n = R_1 \tag{45}$$

$$r_{nb} = R_{b1} \tag{46}$$

$$r_{na} = R_{01} \tag{47}$$

Pressure Angle at Load Application Point.—The critical bending stress on a spur gear tooth develops when all the applied load is carried at the highest point of single tooth contact on the tooth. Spur gears having variations that prevent two pairs of teeth from sharing the load may be stressed most heavily when the load is applied at the tips of the teeth. [Table 1](#) has been used in previous standards to establish the variation in base pitch between the

gear and pinion, which determines whether load sharing exists in steel spur gears. Values greater than those in the table require the use of tip loading in determining bending stress geometry factors described in AGMA 908-B89.

Table 1. Maximum Allowable Variation in Action for Steel Spur Gears for Load Sharing (Variation in Base Pitch)

Number of Pinion Teeth	Load Pounds per Inch of Face (Newtons Per Millimeter of Face)				
	500 lb (90N)	1000 lb (175N)	2000 lb (350N)	4000 lb (700N)	8000 lb (1400N)
	Maximum Allowable Variation in Inches and Millimeters when Teeth Share Load				
15	0.0004 in.	0.0007 in.	0.0014 in.	0.0024 in.	0.0042 in.
	0.01 mm	0.02 mm	0.04 mm	0.06 mm	0.11 mm
20	0.0003 in.	0.0006 in.	0.0011 in.	0.0020 in.	0.0036 in.
	0.01 mm	0.02 mm	0.03 mm	0.05 mm	0.09 mm
25	0.0002 in.	0.0005 in.	0.0009 in.	0.0017 in.	0.0030 in.
	0.01 mm	0.01 mm	0.02 mm	0.04 mm	0.08 mm

For helical gears and spur gears that are analyzed with the load applied at the tip of the tooth, the pressure angle at the load application point, ϕ_{nW} , is found from

$$\tan \phi_{nW} = \left[\left(\frac{r_{na}}{r_{nb}} \right)^2 - 1 \right]^{0.50} \quad (48)$$

For spur gears, where the highest bending stress occurs when the load is at the highest point of single tooth contact (HPSTC), the pressure angle is found from

$$\tan \phi_{nW} = \frac{C_4}{r_{nb}} \quad (49)$$

Equation (49) may also be used for LACR helical gears, but distance C_4 must be based on the virtual spur gear. The following equations are from analogy with Equation (3), (6), (11), (12), (14), (44), and (49):

$$\text{Standard (ref) pitch radius of virtual spur gear, } r_{n2} = r_n m_G \quad (50)$$

$$\text{Virtual base radius, } r_{nb2} = r_{nb} m_G \quad (51)$$

$$\text{Virtual outside radius, } r_{na2} = r_{n2} + R_{02} - R_2 \quad (52)$$

$$\text{Sixth distance along line of action of virtual gear, } C_{n6} = (r_{nb2} + r_{nb}) \tan \phi_{nr} \quad (53)$$

$$\text{First distance along line of action of virtual gear, } C_{n1} = [C_{n6} - (r_{na2}^2 - r_{nb2}^2)^{0.50}] \quad (54)$$

$$\text{Fourth distance along line of action of virtual gear, } C_{n4} = C_{n1} + \rho_N \quad (55)$$

The pressure angle at the load application point (tip), ϕ_{nW}

$$\tan \phi_{nW} = \frac{C_{n4}}{r_{nb}} \quad (56)$$

Generating-Rack Shift Coefficient.—The generating-rack shift coefficient, x_g , applies to the completely finished teeth. It includes the rack shift for addendum modification plus the rack shift for thinning the teeth to obtain backlash:

$$x_g = x - \frac{\Delta s_n}{2 \tan \phi_n} \quad (57)$$

where ΔS_n = amount gear tooth is thinned for backlash and x = addendum modification coefficient at zero backlash,

$$x = \frac{\left(S_n + \Delta S_n - \frac{\pi}{2}\right)}{(2 \tan \phi_n)} \quad (58)$$

where S_n = normal circular tooth thickness measured on the standard (ref) pitch cylinder,

$$S_n = \frac{\pi}{2} + 2x_g \tan \phi_n \quad (59)$$

Load Angle and Load Radius: Fig. 2 defines the load angle ϕ_{nl} and the load radius r_{nl} . The applied load is shown at an arbitrary point W such that:

$$\phi_{nl} = \tan \phi_{nw} - \text{INV} \phi_{np} \quad (60)$$

where ϕ_{np} = pressure angle where gear tooth is pointed, Fig. 3.

$$\text{INV} \phi_{np} = \text{INV} \phi_n + \frac{S_n}{2r_n} \quad (61)$$

but,

$$\text{INV} \phi_n = \tan \phi_n - \phi \quad (62)$$

and

$$2r_n = n \quad (63)$$

so that

$$\text{INV} \phi_{np} = \tan \phi_n - \phi_n + \frac{S_n}{n} \quad (64)$$

Then Equation (60) can be expressed as

$$\phi_{nl} = \tan \phi_{nw} - \tan \phi_n + \phi_n - \frac{S_n}{n} \quad (65)$$

Equation (65) gives the load angle ϕ_{nL} for any load position specified by $\tan \phi_{nw}$ found from Equation (48) and (49).

As may be seen from Fig. 3, the virtual radius is

$$r_{nl} = \frac{r_{nb}}{\cos \phi_{nL}} \quad (66)$$

Tables of Geometry Factors, I and J .—Included here are some of the tables of precalculated values of I and J extracted from the Information Sheet. For additional data, tables, and related information for other combinations of gear sets, tooth forms, pressure angles, helix angles, cutting tool dimensions, and addendum coefficients, refer to the Information Sheet. It should be noted that the formulas and data in the Information Sheet are not applicable to bending stresses in internal gears, since no simplified model for calculating bending stresses in internal gears is available.

Using the Tables.—Each of the tables in the Information Sheet and those presented here were generated for a specific tool form (basic rack) defined by whole depth factor, normal pressure (profile) angle, and tool tip radius. Only those tables applicable to spur gears are presented here; those for helical gear sets are available in the Information Sheet.

Whole Depth: Whole depth is expressed in the tables as a “whole depth factor” and is the whole depth of a basic rack for I normal module or I normal diametral pitch. The actual generated depths will be slightly greater due to tooth thinning for backlash

Outside Diameter: The tabulated values are for gears having an outside diameter (for normal module or normal diametral pitch = 1), equal to

$$D_{a1} = \frac{n_1}{\cos \psi} + 2(1 + x_1) \quad (67)$$

$$D_{a2} = \frac{n_2}{\cos \psi} + 2(1 + x_2) \quad (68)$$

where n_1 and n_2 are the pinion and gear tooth numbers, respectively; ψ = standard helix angle, deg.; and D_{a1} and D_{a2} are the pinion and gear addendum, respectively.

Center Distance: The tables apply to gearsets that operate at standard center distance. This center distance is the tight-mesh center distance for gears not yet thinned for backlash:

$$C = \frac{(n_1 + n_2)}{2 \cos \psi} \quad (69)$$

where C = standard center distance. For this center distance the sum of the addendum modification coefficients for pinion and gear is zero:

$$x_1 + x_2 = 0 \quad (70)$$

Tooth Thickness Backlash Allowance: Values in the tables were calculated based on a backlash allowance. The circular tooth thickness for the pinion and gear are each thinned by an amount Δs_n :

$$\Delta s_n = \frac{0.024}{P_{nd}} = 0.024 \text{ for } P_{nd} = 1 \quad (71)$$

If the gears being evaluated have different minimum tooth thicknesses than from Equation (71), the bending strength geometry factor, J , can be approximated by using Equation (72). The pitting resistance geometry factor, I , is unaffected by variations in tooth thickness:

$$J_1 = J_s \left(\frac{s_{n1}}{s_{ns}} \right)^2 \quad (72)$$

where J_1 = adjusted geometry factor; J_s = geometry factor from table; s_{n1} = adjusted circular tooth thickness; and s_{ns} = standard tooth thickness thinned per Equation (71).

As an example, from Table 4, for 20-deg pressure angle spur gears loaded at the highest point of single tooth contact, the J factor for a 21-tooth pinion operating with a 35-tooth gear is found to be 0.31. The table values are based on a circular tooth thickness of $\pi/2 - 0.024 = 3.1416/2 - 0.024 = 1.547$ for diametral pitch.

For a 10 normal diametral pitch pinion or gear, the equivalent circular tooth thickness would be $1.547/10 = 0.155$.

If a J value for a 0.010 in. thinner pinion, having a circular thickness of $0.155 - 0.010 = 0.145$ in. is required, the approximate value is $0.34(0.145/0.155)^2 = 0.30 = J_1$ so that a 6.5 per cent reduction in tooth thickness reduces the J factor by 12 percent.

Undercutting: The tables do not include geometry factors that may be needed if an undercutting condition exists in either of the two gears. Undercutting can be evaluated using Equation (73) and Fig. 4 where the generating-rack shift coefficient, x_g , must be equal to or greater than the expression in Equation (73):

$$x_{gmin} = h_{ao} - \rho_{ao}(1 - \sin \phi_n) - \left(\frac{n}{2} \right) \sin \phi_n^2 \quad (73)$$

where h_{ao} = nominal tool addendum; ρ_{ao} = tool tip radius; and n = pinion or gear tooth number.

Fig. 4. Undercutting Criteria

Top Land: The tables do not include geometry factors when either the pinion or the gear tooth top land is less than the value expressed in Equation (74) or (74a):

$$s_{namin} \geq \frac{0.3}{P_{nd}} \text{ in.} \quad (74)$$

$$s_{namin} \geq 0.3m_n \text{ mm} \quad (74a)$$

in which s_{na} = tooth thickness at outside diameter.

Cutter Geometry: The hob geometry used in the calculation of I and J is as follows: Tool tooth number, $n_c = 10,000$; reference normal circular tooth thickness of tool, $s_{no} = 1.5708$; addendum modification coefficient of tool, $x_o = 0.0$; amount of protuberance, $\delta_o = 0.0$.

Power-Transmitting Capacity of Spur Gears

Modes of Failure.—When sets of spur gears are made, installed, and lubricated properly, they normally may be subject to three primary modes of failure, as discussed below.

Tooth Scoring: Tooth scoring is a scuffing or welding type of tooth failure, caused by high sliding speed combined with high contact stress. Scoring is not a fatigue failure but rather a failure of the lubricant caused by increases in lubricant viscosity with pressure. The lubricant must provide cooling to the gears as well as reducing friction. Well proportioned commercial gears with a pitchline velocity of less than 7000 ft/min will normally not score if they have a reasonably good surface finish and are properly lubricated. If scoring does occur or if it is suspected to be critical in a new high speed design, the scoring temperature index should be determined by the method shown in American Gear Manufacturers Standard AGMA 217.01 or by some similar method.

Pitting: In surface pitting, small cracks first develop on and under the surfaces of gear teeth as a result of metal fatigue. Pieces of the surface then break away, and those that do not fall clear cause further damage or broken teeth. Vacuum-melted steels have gone far toward reducing pitting. Failure usually occurs at a point just below the pitch surface on the driving pinion and may be anticipated in the gear design by a determination of the gear set contact compressive stress.

Tooth Breakage: Tooth breakage is usually a tensile fatigue failure at the weakest section of the gear tooth when considered as a cantilever beam. The weakest point is normally the tensile side of the gear tooth fillet, and it may be anticipated in the gear design by determining the stress at this weakest section of the gear tooth.

Strength Calculations for Spur and Helical Gears.—Many standards and procedures for the design, manufacture, inspection, and application of gears have been published for the guidance of both the users and the manufacturers of gears and gear products. Among such publications, those of the American Gear Manufacturers Association (AGMA) represent an authoritative resource for information and standards on all phases of design, inspection, manufacture, application, and other aspects of gear technology.

American Gear Manufacturers Association Standard, AGMA 2001–B88, *Fundamental Rating Factors and Calculation Methods for Involute Spur and Helical Gear Teeth*, is a revision of, and supersedes, AGMA 218.01. The Standard presents general formulas for rating the pitting resistance and the bending strength of spur and helical involute gear teeth and is intended to establish a common base for rating various types of gears for differing applications and to encourage the maximum practical degree of uniformity and consistency between rating practices in the gear industry. Standard 2001–B88 provides the basis from which more detailed AGMA Application Standards are developed and is a means for calculation of approximate ratings in the absence of such standards. Where applicable AGMA standards exist, they should be used in preference to this Standard. Where no applicable standards exist, numerical values may be estimated for the factors used in the general equations presented in the standard. The values of these factors may vary significantly, depending on the application, system effects, gear accuracy, manufacturing practice, and definition of what constitutes gear failure. Proper evaluation of these factors is essential for realistic ratings.

Information on the geometry factors, I and J , used in pitting resistance and bending strength calculations has been amplified, and moved from the old AGMA 218.01 standard to AGMA 908–B89, *Geometry Factors for Determining the Pitting Resistance and Bending Strength of Spur, Helical, and Herringbone Gear Teeth*. AGMA Standard 908–B89 is covered on Handbook pages 1853–1866.

Rating Formulas*.—AGMA 2001–B88 provides a method whereby different gear designs can be compared but it is not intended to ensure the performance of assembled gear drive systems. The formulas are applicable for rating the pitting resistance and bending strength of internal and external spur and helical involute gear teeth operating on parallel axes. Gear tooth capacity is influenced by the major factors that affect gear tooth pitting and gear tooth fracture at the fillet radius can be evaluated with these formulas.

Knowledge and judgment required to evaluate the various rating factors can be gained only from years of accumulated experience in designing, manufacturing, and operating gear units. Empirical factors given in the AGMA 2001–B88 standard are general in nature, and other AGMA application standards may use other empirical factors that are more closely suited to the particular field of application. AGMA 2001–B88 is intended for use by the experienced gear designer capable of selecting suitable values for the factors and not for use by engineers inexperienced in gear design and applications.

Exceptions.—The formulas in this Standard are not applicable to other types of gear tooth deterioration such as plastic yielding, wear, case crushing, and welding and are not applicable when vibratory conditions exceed the limits for the normal operation of the gears (see AGMA 6000–A88, *Specification for Measurement of Lateral Vibration on Gear Units*). The formulas are not applicable when any of the following conditions exist:

5) spur gears with transverse contact ratio less than 1.0; 6) spur or helical gears with transverse contact ratio equal to or greater than 2.0; 7) interference exists between the tips of the teeth and the root fillets; 8) the teeth are pointed; and 9) backlash is zero.

Additional Considerations.—When suitable test results or field data are not available, values for the rating factors should be chosen conservatively. Among other considerations, the following should be taken into account:

Manufacturing Tolerances: Rating factors should be evaluated on the basis of the expected variation of component parts in the production run.

Accuracy: Experimental data from actual gear unit measurements are seldom repeatable within a plus or minus 10 per cent band. Calculated gear ratings are intended to be conservative but the scatter in actual results may exceed 20 per cent.

Misalignment and Deflection of Foundations: Misalignment and deflection of foundations, on which many gear systems depend to maintain alignment of the gear mesh, will adversely affect overall performance.

Deflection due to External Loads: Deflection of supporting housings, shafts, and bearings, due to external overhang, transverse and thrust loads affects tooth contact across the mesh. Deflection varies with load, so it is difficult to obtain good tooth contact at different loads. Generally, deflection due to external loads reduces capacity.

Metallurgy: The allowable stress numbers included in the Standard are a function of melting, casting, forging, and heat treating practices. Hardness, tensile strength, and cleanliness are some of the criteria for determining allowable stress numbers; the allowable values in this Standard are based on 10,000,000 cycles of loading, 99 percent reliability, and unidirectional loading.

Variations in microstructure account for some variation in gear capacity. Higher levels of cleanliness and better metallurgical controls permit use of higher allowable stress values and, conversely, lower quality levels require the use of lower values.

Residual Stress: Any material having a case—core relationship is likely to have residual stresses. Properly managed, these stresses will be compressive at the surface and will enhance the bending strength performance of the gear teeth. Shot peening, case carburiz-

*Extracted from AGMA 2001–B88, Fundamental Rating Factors and Calculation Methods for Involute Spur and Helical Gear Teeth, with the permission of the publisher, American Gear Manufacturers Association, 1500 King Street, Suite 201, Alexandria, Virginia 22314.

ing, nitriding, and induction hardening are common methods of inducing compressive prestress in the surfaces of gear teeth.

Grinding the tooth surfaces after heat treatment reduces residual compressive stresses; and grinding the tooth surfaces and the root fillet areas may introduce tensile stresses and possibly cracks in these areas if done incorrectly. Care is needed to avoid excessive reductions in hardness and changes in microstructure during the grinding process, and shot peening after grinding is often performed to ensure the presence of residual compressive stresses.

Lubrication: The ratings determined by the formulas in the Standard are only valid when a lubricant of proper viscosity for the load, gear-tooth surface finish, temperature, and pitchline velocity is used. Gears with pitchline velocities of less than 100 ft/min require special design considerations to avoid premature failure from inadequate lubrication.

Velocities greater than 100 ft/min but less than 1000 ft/min frequently require special design considerations even when the lubricants used conform to AGMA 250 recommendations.

With velocities in the range of 1000–0,000 ft/min, lubrication problems may be caused by high temperatures, unsuitable additives in the oil, size of the pinion, inadequate oil viscosity, or tooth finish characteristics. Problems in this speed range are not common in industrial gears but sometimes occur in aerospace and in marine gearing.

From a lubrication standpoint, the design of slower gears should be based on application criteria such as hours of life, degree of reliability needed, and acceptable increases in vibration and noise as the gear teeth wear or deform. At pitchline velocities below 100 ft/min, or 20 rpm input speed, the gear designer may allow for acceptable pitting and wear to occur during the gear life when using these rating practices for other than surface-hardened gearing. Rating of gear teeth due to wear is not covered by this Standard.

System Dynamics: The dynamic response of the system results in additional gear tooth loads due to the relative motions of the connected masses of the driver and the driven equipment. Application factors, C_a and K_a , are intended to account for the operating characteristics of the driving and driven equipment. However, if the operating roughness of the driver, gearbox, or driven equipment causes an excitation with a frequency near to one of the system's major natural frequencies, resonant vibrations may cause severe overloads that may be several times higher than the nominal load. For more information, refer to AGMA 427.01, *Information Sheet—Systems Considerations for Critical Service Gear Drives*.

Corrosion: Corrosion of the gear tooth surface can have significant detrimental effects on the bending strength and pitting resistance of the teeth. The extent of these corrosion effects is not included in the Standard.

Cold Temperature Operation: For gears operated at temperatures below 320F, special care must be taken to select materials that will have adequate impact properties at the operating temperature. Consideration should be given to

1) low-temperature Charpy impact specification; 2) fracture appearance transition or nil ductility temperature specification; 3) reduction of carbon content to less than 0.4 per cent; and 4) use of higher nickel alloy steels.

Criteria for Gear Tooth Capacity

Relationship of Pitting Resistance and Bending Strength Ratings.—There are two major differences between the pitting resistance and the bending strength ratings. Pitting is a function of the Hertzian contact (compressive) stresses between two cylinders and is proportional to the square root of the applied load. Bending strength is measured in terms of the bending (tensile) stress in a cantilever plate and is directly proportional to this same load. The difference in the nature of the stresses induced in the tooth surface areas and at

the tooth root is reflected in a corresponding difference in allowable limits of contact and bending stress numbers for identical materials and load intensities.

Analysis of the load and stress modifying factors is similar in each instance, so many of these factors have identical numerical values. The term "gear failure" is itself subjective and a source of considerable disagreement. One observer's "failure" may be another observer's "wearing in." A more complete discussion of "failure" is given in AGMA 110.04, Nomenclature of Gear Tooth Failure Modes.

Pitting Resistance: In most industrial practice, corrective and nonprogressive initial pitting is not deemed serious. Initial pitting is characterized by small pits that do not extend over the entire face width or profile height of the affected teeth. The definition of acceptable pitting varies widely with gear application. Initial pitting occurs in localized, overstressed areas and tends to redistribute the load by progressively removing high contact spots. Generally, when the load has been reduced or redistributed, the pitting stops.

The pitting resistance formula aims to determine a load rating at which destructive pitting of the teeth does not occur during their design life. The ratings for pitting resistance are based on the formulas developed by Hertz for contact pressure between two curved surfaces, modified for the effect of load sharing between adjacent teeth.

Bending Strength: The bending strength of gear teeth is a fatigue phenomenon related to the resistance to cracking at the tooth root fillet in external gears and at the critical section in internal gears. The basic theory employed in this analysis assumes the gear tooth to be rigidly fixed at its base, thus, the critical stress occurs in the fillet. If the rim supporting the gear tooth is thin relative to the size of the tooth and the gear pitch diameter, another critical stress may occur not at the fillet but in the root area. The rim thickness factor, K_B , adjusts the calculated bending stress number for thin rimmed gears.

The strength ratings determined by this Standard are based on plate theory that is modified to consider:

- 1) the compressive stress at tooth roots caused by the radial component of tooth loading;
- 2) nonuniform moment distribution resulting from the inclined angle of the load lines on the teeth; 3) stress concentrations at the tooth root fillets; and 4) the load sharing between adjacent teeth in contact.

The intent of the AGMA strength rating formula is to determine the load that can be transmitted for the design life of the gear drive without causing cracking or failure. Occasionally, wear, surface fatigue, or plastic flow may limit bending strength due to stress concentrations around large, sharp cornered pits or wear steps on the tooth surface.

Fundamental Rating Formulas.—The symbols and definitions used in the pitting resistance and bending strength formulas are shown in [Table 1](#). SI units are shown in parentheses in [Table 1](#) and in the text. Where equations require a different format or constant for use with SI units, a second expression is shown after the first and with M included in the equation number at the right.

Pitting Resistance.—The fundamental formula for pitting resistance of gear teeth is

$$S_c = C_p \sqrt{\frac{W_t \times C_a \cdot C_s \cdot C_m \times C_f}{C_v \cdot dF \cdot I}} \quad (1)$$

where the meaning of the symbols is as shown in [Table 1](#) and,

$$d = \frac{2C}{m_G + 1.0} \quad \text{for external gears} \quad (2)$$

$$d = \frac{2C}{m_G - 1.0} \quad \text{for internal gears} \quad (3)$$

Table 1. Symbols Used in Gear Rating Equations

Symbol	Description of Symbols and Units	Symbol	Description of Symbols and Units
C	Operating center distance, in. (mm)	K_R	Reliability factor for bending strength
C_a	Application factor for pitting resistance	K_s	Size factor for bending strength
C_c	Curvature factor at pitchline	K_{SF}	Service factor for bending strength
C_e	Mesh alignment correction factor	K_T	Temperature factor for bending strength
C_f	Surface condition factor for pitting resistance	K_v	Dynamic factor for bending strength
C_G	Gear ratio factor	K_y	Yield strength factor
C_H	Hardness ratio factor for pitting resistance	m	Metric module, nominal in plane of rotation (mm)
C_L	Life factor for pitting resistance	m_B	Back up ratio
C_m	Load distribution factor for pitting resistance	m_G	Gear ratio (never less than 1.0)
C_{ma}	Mesh alignment factor	m_N	Load sharing ratio
C_{mc}	Lead correction factor	m_n	Normal metric module, nominal (mm)
C_{mf}	Face load distribution factor	N	Number of load cycles
C_{mt}	Transverse load distribution factor	N_G	Number of teeth in gear
C_p	Elastic coefficient [lb/in. ²] ^{0.5} (MPa) ^{0.5}	N_p	Number of teeth in pinion
C_{pf}	Pinion proportion factor	n_p	Pinion speed rpm
C_{pm}	Pinion proportion modifier	P	Transmitted power, hp (kW)
C_R	Reliability factor for pitting resistance	P_{ac}	Allowable transmitted power for pitting resistance, hp (kW)
C_s	Size factor for pitting resistance	P_{at}	Allowable transmitted power for bending strength, hp (kW)
C_{SF}	Service factor for pitting resistance	P_d	Diametral pitch, nominal, in plane of rotation, in ⁻¹
C_T	Temperature factor for pitting resistance	P_{nd}	Normal diametral pitch, nominal, in ⁻¹
C_v	Dynamic factor for pitting resistance	P_b	Transverse base pitch, in. (mm)
C_x	Contact height factor	P_x	Axial pitch, in. (mm)
C_ψ	Helical overlap factor	Q_v	Transmission accuracy level number
d	Operating pitch diameter of pinion, in. (mm)	S	Bearing span, in. (mm)
E_G	Modulus of elasticity for gear, lb/in. ² (MPa)	S_l	Pinion offset, in. (mm)
E_p	Modulus of elasticity for pinion, lb/in. ² (MPa)	S_{ac}	Allowable contact stress number, lb/in. ² (MPa)
e_t	Total lead mismatch, in. (mm)	S_{at}	Allowable bending stress number, lb/in. ² (MPa)

Table 1. (Continued) Symbols Used in Gear Rating Equations

Symbol	Description of Symbols and Units	Symbol	Description of Symbols and Units
f_p	Pinion surface finish, microinches rms	S_{ay}	Allowable yield stress number, lb/in. ² (MPa)
F	Net face width of narrowest member, in. (mm)	S_c	Contact stress number, lb/in. ² (MPa)
G	Tooth stiffness constant, lb/in. ² (MPa)	S_t	Bending stress number, lb/in. ² (MPa)
H_{BG}	Brinell hardness of gear	T	Transmitted pinion torque, lb-in. (N-m)
H_{BP}	Brinell hardness of pinion	t_R	Gear rim thickness, in. (mm)
h_c	Minimum total case depth for nitrided gears, in. (mm)	t_o	Normal tooth thickness at top land of gear, in. (mm)
h_e	Minimum effective case depth for carburized gears, in. (mm)	U_{at}	Allowable unit load for bending strength, lb/in. ² (MPa)
$h_{e\ max}$	Maximum effective case depth, in. (mm)	U_c	Core hardness coefficient
h_t	Gear tooth whole depth, in. (mm)	U_H	Hardening process factor
I	Geometry factor for pitting resistance	U_L	Unit load for bending strength, lb/in. ² (MPa)
J	Geometry factor for bending strength	v_t	Pitch line velocity at operating pitch diameter, ft/min (m/s)
K	Contact load factor for pitting resistance, lb/in. ² (MPa)	$v_{t\ max}$	Pitch line velocity maximum at operating pitch diameter, ft/min (m/s)
K_a	Application factor for bending strength	W_d	Incremental dynamic tooth load, lb (N)
K_{ac}	Allowable contact load factor, lb/in. ² (MPa)	W_{max}	Maximum peak tangential load, lb (N)
K_B	Rim thickness factor	W_t	Transmitted tangential load, lb (N)
K_f	Stress correction factor	Y	Tooth form factor
K_L	Life factor for bending strength	Z	Length of action in transverse plane, in. (mm)
K_m	Load distribution factor for bending strength	μ_G	Poisson's ratio for gear
		μ_P	Poisson's ratio for pinion
		ϕ_t	Operating transverse pressure angle
		ψ_s	Helix angle at standard pitch diameter
		ψ_b	Base helix angle

Allowable Contact Stress Number: The relation of calculated contact stress number (graphed in Fig. 1) to the allowable contact stress number is

$$S_c \leq S_{ac} \frac{C_L C_H}{C_T C_R} \quad (4)$$

Fig. 1. Allowable Contact Stress Number for Steel Gears, S_{ac}

Pitting Resistance Power Rating.—The pitting resistance power rating is given by

$$P_{ac} = \frac{n_p \times F}{12600 C_s \times C_m \times C_f \times C_a} \frac{I \times C_v}{C_p \times C_T \times C_R} \left(\frac{d \times S_{ac} C_L \times C_H}{C_p \times C_T \times C_R} \right)^2 \tag{5}$$

$$P_{ac} = \frac{n_p \times F}{1.91 \times 10^7 C_s \times C_m \times C_f \times C_a} \frac{I \times C_v}{C_p \times C_T \times C_R} \left(\frac{d \times S_{ac} C_L \times C_H}{C_p \times C_T \times C_R} \right)^2 \tag{5a}$$

In using [Formula \(5\)](#) and [\(5a\)](#), the ratings of both pinion and gear must be calculated to evaluate differences in material properties and the number of cycles under load. The pitting resistance power rating is based on the lowest value of the product $S_{ac} C_L C_H$ for each of the mating gears.

Contact Load Factor, K .—In some industries, pitting resistance is rated in terms of a K factor:

$$K = \frac{W_t}{dF} \times \frac{1}{C_G} \tag{6}$$

for external gears, $C_G = \frac{N_G}{N_G + N_P}$ (7)

for internal gears, $C_G = \frac{N_G}{N_G - N_P}$ (8)

In terms of this Standard, the allowable K factor is defined as

$$K_{ac} = \frac{I}{C_G C_a \times C_s \times C_m \times C_f} \frac{C_v}{C_p \times C_T \times C_R} \left(\frac{S_{ac} \times C_L \times C_H}{C_p \times C_T \times C_R} \right)^2 \tag{9}$$

The allowable contact load factor, K_{ac} , is the lowest of the ratings calculated using the different values of S_{ac} , C_L , and C_H for pinion and gear.

Bending Strength.—The fundamental formula for bending stress number in a gear tooth is

$$s_t = \frac{W_t \times K_a P_d K_s \times K_m \times K_B}{K_v F J} \tag{10}$$

where $P_d = P_{nd}$ for spur gears. For helical gears, P_d is given by Equation (11),

$$s_t = \frac{W_t \times K_a I K_s \times K_m \times K_B}{K_v F \times m J} \tag{10a}$$

where $m = m_n$ for spur gears. For helical gears m is given by Equation (11a):

$$P_d = \frac{\pi}{p_x \tan \psi_s} = P_{nd} \cos \psi_s \tag{11}$$

$$m = \frac{P_x \times \tan \psi_s}{\pi} = \frac{m_n}{\cos \psi_s} \tag{11a}$$

where ψ_s is given by Equation (12) or (12a)

$$\psi_s = \text{asin} \left(\frac{\pi}{p_x \times P_{nd}} \right) \tag{12}$$

$$\psi_s = \text{asin} \left(\frac{\pi \times m_n}{p_x} \right) \tag{12a}$$

Allowable Bending Stress Number.—The relation of calculated bending stress number to allowable bending stress number is

$$S_t \leq \frac{S_{at} \times K_L}{K_T \times K_R} \tag{13}$$

Fig. 2. Allowable Bending Stress Number for Steel Gears s_{at}

Bending Strength Power Rating.—The bending strength power rating is

$$P_{at} = \frac{n_p \times d \times K_v}{126000 \times K_a P_d K_s \times K_m \times K_B K_R \times K_T} \frac{F}{J} \frac{s_{at} \times K_L}{K_T} \quad (14)$$

$$P_{at} = \frac{n_p \times d \times K_v}{1.91 \times 10^7 \times K_a} \frac{F \times m \times J}{K_s \times K_m \times K_B K_R \times K_T} \frac{s_{at} \times K_L}{K_T} \quad (14a)$$

The ratings of both pinion and gear must be calculated to evaluate differences in geometry factors, number of load cycles, and material properties. The bending strength power rating is based on the lowest value of the term $s_{at} K_L J / K_B$ for each of the mating gears.

In some industries, the bending strength is rated in terms of unit load:

$$U_L = \frac{(W_t \times P_{nd})}{F} \quad (15)$$

$$U_L = \frac{W_t}{(F \times m)} \quad (15a)$$

The allowable unit load, U_{at} , is the lowest of the ratings calculated using the different values of s_{at} , K_B , K_L , and J for pinion and gear in Equation (16):

$$U_{at} = \frac{J}{\cos \psi K_a \times K_m \times K_s \times K_B K_R \times K_T} \frac{K_v}{s_{at} \times K_L} \quad (16)$$

Values for Factors Applied in Fundamental Equations.—Values for the various factors used in the pitting resistance and bending strength rating equations are discussed and explained in greater detail in the Standard and its appendices than can be provided here. The following paragraphs are intended by the Editors to provide values for some of these factors suitable for making approximations to the ratings of pairs of mating gears without the refinements used by experienced gear designers.

Rim Thickness Factor K_B .—The rim thickness factor, K_B , is used to adjust the calculated bending stress number for thin rimmed gears, the value of the factor depending upon the backup ratio,

$$m_B = \frac{t_R}{h_t} \quad (17)$$

If m_B is equal to or greater than 1.2, then K_B may be taken as 1.0. For values of m_B less than 1.2, see the information in Appendix C following the Standard.

Geometry Factors I and J .—The geometry factors I and J for pitting resistance and bending strength, respectively, are described, along with selected typical values, beginning on page 1853.

Transmitted Tangential Load, W_t .—In most gear applications the torque is not constant, so the transmitted tangential load will vary. To obtain values of the operating transmitted tangential load, W_t , the values of power and speed at which the driven device will operate should be used. If the rating is calculated on the basis of uniform load, then the transmitted tangential load is

$$W_t = \frac{33000 \times P}{v_t} = \frac{2 \times T}{d} = \frac{126000 \times P}{n_p \times d} \quad (18)$$

$$W_t = \frac{1000 \times P}{v_t} = \frac{2000 \times T}{d} = \frac{1.91 \times 10^7 \times P}{n_p \times d} \quad (18a)$$

where,

$$v_t = \frac{(\pi \times n_p \times d)}{12} \quad (19)$$

$$v_t = \frac{(\pi \times n_p \times d)}{60000} \quad (19a)$$

Nonuniform Load: When the transmitted load is not uniform, consideration should be given not only to the peak load and its anticipated number of cycles, but also to intermediate loads and their duration. This type of load is often considered a duty cycle and may be represented by a load spectrum. The cumulative fatigue effect of the duty cycle is then considered in rating the gearset. A method of calculating the effects of the loads under such conditions is given in Appendix B of the Standard.

Dynamic Factors, C_v and K_d .—Dynamic factors account for internally generated gear tooth loads, which are induced by nonconjugate meshing action of the gear teeth. Even if the input torque and speed are constant, significant vibration of the gear masses, and therefore dynamic tooth forces, can exist. These forces result from the relative displacements between the gears as they vibrate in response to an excitation known as “transmission error.” Ideally, a gearset would have a uniform velocity ratio between the input and output rotation. Transmission error is defined as the departure from uniform relative angular motion of the pair of meshing gears. It is influenced by all the deviations from the ideal gear tooth form.

The dynamic factor relates the total tooth load, including internal dynamic effects, to the transmitted tangential tooth load:

$$C_v = K_v = \frac{W_t}{W_d \times W_t} \quad (20)$$

where W_d = incremental dynamic tooth load due to the dynamic response of the gear pair to the transmission error excitation, excluding the transmitted tangential load W_t .

Excitation: The transmission error contributing to the dynamic factors is influenced by:

- 1) Manufacturing variations such as spacing, profile, lead, and runout.
- 2) Gear mesh stiffness variation as the gear teeth pass through the meshing cycle. This source of excitation is especially pronounced in spur gears without profile modification. Spur gears with properly designed profile modification, and helical gears with axial contact ratios greater than 1.0, have a smaller stiffness variation.
- 3) Transmitted load. Since elastic deflections are load dependent, gear tooth profile modifications can be designed to give a uniform velocity ratio at only one load magnitude.
- 4) Pitchline velocity. The frequencies of the excitation depend on the pitchline velocity.
- 5) Dynamic imbalance of the gears and shafts.
- 6) Excessive wear and plastic deformation of the gear tooth profiles increase the amount of transmission error.
- 7) Shaft alignment. Gear tooth alignment is influenced by load and thermal distortions of the gears, shafts, bearings, and housings, and by manufacturing variations.
- 8) Tooth friction induced excitation.

Dynamic Response: The dynamic tooth forces are influenced by:

- 1) Mass of the gears, shafts, and other major internal components.
- 2) Stiffness of the gear teeth, gear blanks, shafts, bearings, and gear housings.
- 3) Damping. The principal source of coulomb or viscous damping is the shaft bearings. Generally, oil film bearings provide greater damping than rolling element bearings. Other sources of damping include the hysteresis of the gear shafts, and viscous damping at sliding interfaces and shaft couplings.

Resonance: When an excitation frequency coincides with a natural frequency, the resonant response is limited only by the damping, and high dynamic loads may result. The dynamic factors C_v and K_d do not apply to resonance.

Gear Pair Resonance: If a particular frequency of the transmission error excitation is close to the natural frequency of the gear masses, or some multiple of the natural frequency such as $\frac{1}{2}$ or 2, a resonant vibration may cause high dynamic tooth forces due to large relative displacements of the gear masses. The dynamic factors C_v and K_d do not account for gear pair resonance and operation in this regime is to be avoided.

Gear Blank Resonance: Gear blanks may have natural frequencies within the operating speed range. If the gear blank is excited by a frequency that is close to one of its natural frequencies, the resonant deflections may cause high dynamic tooth loads. This phenomenon occurs more frequently in high speed, light weight gear blanks, but can also occur in other thin rimmed or thinwebbed blanks. The dynamic factors C_v and K_d do not account for gear blank resonance. A separate investigation is recommended when these conditions arise.

System Resonance: The gearbox is one component of a system comprised of a power source, gearbox, driven equipment, and interconnecting shafts and couplings. The dynamic response of this system depends on the distribution of the masses, stiffness, and damping. In certain designs, a system may possess a torsional natural frequency close to an excitation frequency associated with an operating speed. Under these resonant conditions the dynamic tooth loads may be high, and operation near such a system resonance is to be avoided. The dynamic factors C_v and K_d do not include considerations of the dynamic loads due to torsional vibration of the gear system. These loads must be included with other externally applied forces in the application factors C_a and K_a . For critical drives, a separate dynamic analysis of the entire system is recommended.

Shaft Critical Speeds: Owing to their high bending stiffness, the natural frequency of lateral vibrations of the gear shafts are usually much higher than the operating speeds. However, for high speed gears it is recommended that the critical speeds be analyzed to ensure that they are well removed from the operating speed range. The dynamic factors C_v and K_d do not account for the dynamic tooth loads due to this mode of vibration.

Nonlinear Resonance: Large cyclical variation in gear mesh stiffness and impact loads may lead to additional regions of resonance and instability. This problem appears primarily with lightly loaded, lightly damped spur gears that do not have profile modifications.

Approximate Dynamic Factors: Fig. 3 shows dynamic factors that can be used in the absence of specific knowledge of the dynamic loads. The curves of Fig. 3 are based on equations in the Standard derived from empirical data and do not account for resonance.

Choice of which of curves 5 through 11 of Fig. 3 to use should be based on transmission error. When transmission error data are unavailable, it is reasonable to use pitch (spacing) and profile accuracy. Q_v is the transmission accuracy level number. It can be the same as the quality number for the lowest quality member in the mesh from AGMA 2000–A88 when manufacturing techniques ensure equivalent transmission accuracy, or when the pitch (spacing) and profile accuracy are the same as AGMA 2000–A88 tolerances.

Owing to the approximate nature of the empirical curves and the lack of measured tolerance values at the design stage, the dynamic factor curve should be selected based on experience with the manufacturing methods and operating considerations of the design.

The curves in Fig. 3 are referenced only by spacing and profile, and actual dynamic load is influenced by many other factors, so slight variations from the selected tolerances are not considered significant to the gearset rating.

Fig. 3. Dynamic Factors, C_v and K_d

Very Accurate Gearing: Where gearing is manufactured using process controls that correspond to $Q_v \geq 12$ limits, or where the design and manufacturing techniques ensure a low transmission error equivalent to this accuracy, values of C_v and K_d between 0.90 and 0.98 may be used, depending on the specifier's experience with similar applications and the degree of accuracy actually achieved. To use these values, the gearing must be maintained in accurate alignment and adequately lubricated so that its accuracy is maintained under the operating conditions. Spur gears should have properly designed profile modification and helical gears should have an axial contact ratio greater than 1.0.

Curves Numbered 6 through 11 on Fig. 3: These curves are generated by equations in the Standard for values of Q_v , such that $6 \leq Q_v \leq 11$.

Unity Dynamic Factor: When the known dynamic loads (from analysis or experience) are added to the nominal transmitted load, then the dynamic factor can be taken to be 1.0.

Application Factors, C_a and K_a .—These application factors make allowance for any externally applied loads in excess of the nominal tangential load W_t . Application factors can only be established after considerable field experience is gained in a particular application.

In determining the application factor, consideration should be given to the fact that many prime movers develop momentary peak torques appreciably greater than those determined by the nominal ratings of either the prime mover or the driven equipment. Many possible sources of overload should be considered. Some of these are system vibrations, acceleration torques, overspeeds, variations in system operation, split path load sharing among multiple prime movers, and changes in process load conditions. When operating near a critical speed of the drive system, a careful analysis of conditions must be made.

Service Factors, C_{SF} and K_{SF} .—These service factors have been used to include the combined effects of C_L , C_R , C_a and K_L , K_R , K_a , respectively, in an empirically determined single factor. The mathematical contribution of each of these factors has not been established, so that, in the absence of more specific load data, a service factor may be used. When a ser-

vice factor is used, the power rating formulas [Equation (5) and (5a)] would be modified as follows:

$$P_{ac} = \frac{n_p \times F}{126000 C_{sf} \times C_s \times C_m \times C_f} \frac{I \times C_v}{C_p} \left(\frac{d \times s_{ac} C_H}{C_T} \right) \quad (21)$$

$$P_{ac} = \frac{n_p \times F}{1.91 \times 10^7 C_{sf} \times C_s \times C_m \times C_f} \frac{I \times C_v}{C_p} \left(\frac{d \times s_{ac} C_H}{C_T} \right) \quad (21a)$$

$$P_{at} = \frac{n_p \times d \times K_v}{126000 \times K_{SF} P_d K_s \times K_m \times K_B K_T} \frac{F}{J} \frac{s_{at}}{K_T} \quad (22)$$

$$P_{at} = \frac{n_p \times d \times K_v}{1.91 \times 10^7 \times K_{SF} K_s \times K_m \times K_B K_T} \frac{F \times m \times J}{J} \frac{s_{at}}{K_T} \quad (22a)$$

where C_{SF} and K_{SF} are service factors for pitting resistance and bending strength, respectively.

Teeth of both the pinion and the gear must be checked to account for differences in material properties, geometry factors, and the number of cycles under load. The power rating is then based on the lowest values of the following expressions for each of the mating gears:

$$\text{for pitting resistance } \frac{(s_{ac} \times C_H)^2}{C_{SF}}, \text{ and for bending strength } \frac{s_{at} \times J}{K_{SF}}.$$

Elastic Coefficient, C_p .—The elastic coefficient, C_p , is defined by the equation

$$C_p = \sqrt{\frac{1.0}{\pi \left[\left(\frac{1.0 - \mu_P^2}{E_P} \right) \div \left(\frac{1.0 - \mu_G^2}{E_G} \right) \right]}} \quad (23)$$

The value of C_p for a steel gear meshing with a steel pinion is 2300 [lb/in.²]^{0.5}, or 191 (MPa)^{0.5}, approximately. Approximate values for other combinations of materials are given in the Standard.

Surface Condition Factor, C_f .—The surface finish factor used only in the pitting resistance formulas has not yet been established for conditions where there is a detrimental surface finish effect. Where such effects are encountered, a surface condition factor greater than unity should be used.

Size Factors, C_s and K_s .—The size factor reflects nonuniformity of material properties and depends primarily on tooth size, diameter of parts, ratio of tooth size to diameter of part, face width, area of stress pattern, ratio of case depth to tooth size, and hardenability and heat treatment of materials. Size factors have not yet been established for conditions where there is a detrimental size effect, but the factor may be taken as unity for most gears provided that a proper choice of steel is made for the size of the part and its heat treatment and hardening processes.

Load Distribution Factors, C_m and K_m .—The load distribution factor modifies the rating equations to reflect the nonuniform distribution of the load along the lines of contact. The amount of nonuniformity of the load distribution is caused by, and is dependent on the following influences:

- 1) The gear tooth manufacturing accuracy: lead, profile, and spacing;
- 2) alignment of the axes of rotation of the pitch cylinders of the mating gear elements;

3000 POWER TRANSMITTING CAPACITY OF SPUR GEARS

- 3) elastic deflections of gear unit elements: shafts, bearings, housings, and foundations that support the gear elements;
- 4) bearing clearances;
- 5) Hertzian contact and bending deformations at the tooth surface;
- 6) thermal expansion and distortion due to operating temperature (especially on wide face gearing);
- 7) centrifugal deflections due to operating speed;
- 8) tooth crowning and end relief.

Any of these influences that affect a given application should be evaluated by appropriate analysis when possible.

Values for C_m and K_m : The load distribution factor is defined to be the peak load intensity divided by the average, or uniformly distributed load intensity; i.e., the ratio of peak to mean loading. The magnitude is influenced by two components, namely, C_{mf} = face load distribution factor and C_{mt} = transverse load distribution factor that accounts for nonuniform load sharing among load sharing teeth. The load distribution factor is affected primarily by the correctness of the profiles of mating teeth, i.e., profile modification and profile error. The value of the factor may be taken as 1.0 because the Standard has not yet established procedures to evaluate its influence. If C_{mt} is taken as 1.0, then $C_m = K_m = C_{mf}$.

The face load distribution factor C_{mf} accounts for the nonuniform distribution of load across the gearing face width. The magnitude of C_{mf} is defined as the peak load intensity divided by the average load intensity across the face width. Two methods of determining C_{mf} are given in the Standard, an empirical method and an analytical method. These two methods sometimes yield significantly different results.

Empirical Method: The empirical method requires a minimum amount of information and is recommended for relatively stiff designs that meet the following requirements:

- 1) Ratio of net face width to pinion pitch diameter is less than or equal to 2.0;
- 2) the gear elements are mounted between bearings (not overhung);
- 3) face width up to 40 in.; and
- 4) contact across full face width of narrowest member when loaded.

Other restrictions apply to the use of this method. For details of these restrictions and how the method is applied, the Standard should be consulted.

Analytical Method: This method is based on theoretical calculation of values of elastic tooth deformation under load and lead mismatch. Knowledge of the design, manufacturing, and mounting are required to evaluate the load distribution factor. Calculated results should be compared with past experience as it may be necessary to reevaluate other rating factors to arrive at a rating consistent with past experience. As explained in the Standard, the analytical method assumes that mismatch between the teeth is a straight line. This approach usually yields load distribution factors larger than those used in the past. Another method, using true deflection between the teeth (which is not straight line deflection), has resulted in calculated values closer to those used in the past, but it has not been demonstrated that either method is more accurate. Further study may produce other, more accurate, methods.

In using the analytical method, if high values of the gear tooth stiffness constant are used ($G = 2,000,000$) or high values of total lead mismatch e_t are assumed, the C_{mf} values calculated will be much more conservative than those obtained by the empirical method. If C_{mf} values calculated are in excess of 2.0, indicating less than full face contact, it may be desirable to revise the design by improving the configuration of bearings, shaft diameters, aspect ratio, and center distance to lower C_{mf} . It may be possible to lower C_{mf} by modifying leads of the parts. The assumed values of e_t and G have a large effect on C_{mf} , so there are times when experimental verification of C_{mf} may be necessary.

The analytical method is valid for any gear design and is recommended for the following conditions:

1) ratio of net face width to pinion pitch diameter, F/D , is equal or greater than 2.0 (for double helical gears the gap is not included in the face width); 2) applications with overhanging gear elements; 3) applications with long shafts subject to large deflections or where deflections under load reduce width of contact; and 4) applications where contact does not extend across the full face of narrowest member when loaded.

For designs that have high crowns to centralize tooth contact under deflected conditions, the factors C_m and K_m may be conservatively approximated by this method. For the most commonly encountered condition, contact across the entire face width under normal operating load, the face load distribution factor expressions are

$$\text{for spur gearing: } C_{mf} = 1.0 + \frac{G \times e_t \times F}{2 \times W_t} \quad (24)$$

$$\text{and, for helical gearing: } C_{mf} = 1.0 + \frac{G \times e_t \times Z \times F}{1.8 \times W_t} \quad (25)$$

If the total contact length under normal operating load is less than the face width, the expressions for the load distribution factor are

$$\text{for spur gearing: } C_{mf} = \sqrt{\frac{2.0 \times G \times e_t \times F}{W_t}} \quad (26)$$

$$\text{and, for helical gearing: } C_{mf} = \sqrt{\frac{2.0 \times G \times e_t \times Z \times F}{W_t \times P_b}} \quad (27)$$

where G = tooth stiffness constant, lb/in./in. of face (MPa), the average mesh stiffness of a single pair of teeth in the normal direction. The usual range of this value that is compatible with this analysis is $1.5\text{--}2.0 \times 10^6$ lb/in.² ($1.0\text{--}1.4 \times 10^4$ MPa). The most conservative value is the highest. e_t = total lead mismatch between mating teeth, in loaded condition, in. (mm). Z = length of action in transverse plane, from Equation (17) on page 2995, in. (mm). P_b = transverse base pitch, in. (mm).

The total mismatch, e_p , is a virtual separation between the tooth profiles at the end of the face width which is composed of the static, no load separation plus a component due to the elastic load deformations. This total mismatch is influenced by all the items listed under Load Distribution Factors except the Hertzian contact stress and bending deformations of the gear teeth, which are accounted for by the tooth stiffness constant G . Evaluation of e_p is difficult but it is critical to the reliability of the analytical method. An iterative computer program may be used, but in critical applications full scale testing may be desirable.

Allowable Stress Numbers, S_{ac} and S_{at} .—The allowable stress numbers depend on

1) material composition and cleanliness; 2) mechanical properties; 3) residual stress; 4) hardness and; and 5) type of heat treatment, surface or through hardened.

An allowable stress number for unity application factor, 10 million cycles of load application, 99 per cent reliability and unidirectional loading, is determined or estimated from laboratory and field experience for each material and condition of that material. This stress number is designated S_{ac} and S_{at} . The allowable stress numbers are adjusted for design life cycles by the use of life factors.

The allowable stress numbers for gear materials vary with material composition, cleanliness, quality, heat treatment, and processing practices. For materials other than steel, a range is shown, and the lower values should be used for general design purposes. Data for materials other than steel are given in the Standard.

Allowable stress numbers for steel gears are established by specific quality control requirements for each material type and grade. All requirements for the quality grade must be met in order to use the stress values for that grade. Details of these quality requirements are given in the Standard.

Reverse Loading: For idler gears and other gears where the teeth are completely reverse loaded on every cycle, 70 per cent of the S_{at} values should be used.

Fig. 4. Effective Case Depth for Carburized Gears, h_e

Case Depth of Surface-Hardened Gears.—The Standard provides formulas to guide the selection of minimum effective case depth at the pitchline for carburized and induction hardened teeth based on the maximum shear from contact loading.

Fig. 5. Minimum Total Case Depth for Nitrided Gears, h_c

Fig. 5 shows values that have a long history of successful use for carburized gears and can be used for such gears.

For nitrided gears, case depth is specified as the total case depth h_c , which is defined as the depth below the surface at which the hardness has dropped to 10 per cent of the core hardness. Minimum total case depths for nitrided gears are shown in Fig. 5.

Momentary Overloads.—When the gear is subjected to less than 100 cycles of momentary overloads, the maximum allowable stress is determined by the allowable yield properties rather than the bending fatigue strength of the material. Fig. 6 shows suggested values of the allowable yield strength S_{ay} for through hardened steel. For case hardened gears, the core hardness should be used in conjunction with the table of metallurgical factors affecting the bending stress number for carburized gears shown in the Standard.

Fig. 6. Allowable Yield Strength Number for Steel Gears, S_{ay}

The design should be checked to make sure that the teeth are not permanently deformed. Also, when yield is the governing stress, the stress correction factor K_f is considered ineffective and therefore taken as unity.

Yield Strength.—For through hardened gears up to 400 BHN, a yield strength factor K_y can be applied to the allowable yield strength taken from Fig. 6. This factor is applied at the maximum peak load to which the gear is subjected:

$$S_{ay} \times K_y \geq \frac{W_{max} \times K_a P_d K_s \times K_m}{K_v F J \times K_f} \quad (28)$$

$$S_{ay} \times K_y \geq \frac{W_{max} \times K_a \times K_s \times K_m}{K_v \times F \times m \times J \times K_f} \quad (28a)$$

For conservative practice, K_y is taken as 0.5 and for industrial practice, K_y is 0.75.

Hardness Ratio Factor C_H .—The hardness ratio factor depends on (1) gear ratio and (2) Brinell hardness numbers of gear and pinion. When the pinion is substantially harder than the gear, the work hardening effect increases the gear capacity. Typical values of the hard-

ness ratio factor, C_H , for through hardened gears are shown in Fig. 7. These values apply to the gear only, not to the pinion.

When surface hardened pinions (48 HRC or harder) are run with through hardened gears (180–400 BHN), a work hardening effect is achieved. The C_H factor varies with the surface finish of the pinion, K_p , and the mating gear hardness as shown in Fig. 8.

Fig. 7. Hardness Ratio Factor, C_H (Through Hardened)

Life Factors C_L and K_L .— These life factors adjust the allowable stress numbers for the required number of cycles of operation. In the Standard, the number of cycles, N , is defined as the number of mesh contacts under load of the gear tooth being analyzed. Allowable stress numbers are established for 10,000,000 tooth load cycles at 99 per cent reliability. The life cycle factors adjust the allowable stress numbers for design lives other than 10,000,000 cycles.

The life factor accounts for the S/N characteristics of the gear material as well as for the gradually increased tooth stress that may occur from tooth wear, resulting in increased dynamic effects and from shifting load distributions that may occur during the design life of the gearing. A C_L or K_L value of 1.0 may be used beyond 10,000,000 cycles, where justified by experience.

Life Factors for Steel Gears: Insufficient data exist to provide accurate life curves for every gear and gear application. However, experience suggests life curves for pitting and strength of steel gears are as shown in Figs. 9 and 10. These figures do not include data for nitrided gears. The upper portions of the shaded zones are for general commercial applications. The lower portions of the shaded zones are typically used for critical service applications where little pitting and tooth wear are permissible and where smoothness of operation and low vibration levels are required. When gear service ratings are established by the use

Fig. 8. Hardness Ratio Factor, C_H (Surface Hardened Pinions)

of service factors, life factors C_L and K_L should be set equal to 1.0 for the determination of the gear tooth rating.

Localized Yielding.—If the product of $S_{at} K_L$ exceeds the allowable yield stress S_{ay} of Fig. 6, localized yielding of the teeth may occur. In some applications this yielding is not acceptable. In others, where profile and motion transmission accuracies are not critical, the yielding may be acceptable for limited life.

Reliability Factors, C_R and K_R .—These reliability factors account for the effect of the normal statistical distribution of failures found in materials testing. The allowable stress numbers given in the tables in the Standard are based on a statistical probability of 1 failure in 100 at 10,000,000 cycles. Table 2 contains reliability factors which may be used to modify these allowable stresses to change that probability. These numbers are based on data developed for bending and pitting failure by the U.S. Navy. Other values may be used if specific data are available.

When strength rating is based on yield strength, S_{ay} the values of K_y given in the paragraph, Yield Strength, should be used instead of K_R .

Temperature Factors C_T and K_T .—The temperature factor is generally taken as 1 when gears operate with temperatures of oil or gear blank not over 250°F (120°C). At temperatures above 250°F, the factors are given a value greater than 1.0 to allow for the effect of temperature on oil film and material properties. Consideration must be given to the loss of hardness and strength of some materials due to the tempering effect of temperatures over 350°F (175°C).

Fig. 9. Pitting Resistance Life Factor, C_L

Fig. 10. Bending Strength Life Factor, K_L

Table 2. Reliability Factors, C_R and K_R

Requirement of Application	C_R, K_R^a	Requirement of Application	C_R, K_R
Fewer than 1 failure in 10,000	1.50	Fewer than 1 failure in 100	1.00
Fewer than 1 failure in 1,000	1.25	Fewer than 1 failure in 10	0.85 ^b

^aTooth breakage is sometimes considered a greater hazard than pitting. In such instances a value of K_R greater than C_R is selected.

^bAt this value plastic flow might occur rather than pitting.

Worm Gearing

Worm Gearing Classification.—Worm gearing may be divided into two general classes, fine-pitch worm gearing, and coarse-pitch worm gearing. Fine-pitch worm gearing is segregated from coarse-pitch worm gearing for the following reasons:

- 1) Fine-pitch worms and wormgears are used largely to transmit motion rather than power. Tooth strength except at the coarser end of the fine-pitch range is seldom an important factor; durability and accuracy, as they affect the transmission of uniform angular motion, are of greater importance.
- 2) Housing constructions and lubricating methods are, in general, quite different for fine-pitch worm gearing.
- 3) Because fine-pitch worms and wormgears are so small, profile deviations and tooth bearings cannot be measured with the same accuracy as can those of coarse pitches.
- 4) Equipment generally available for cutting fine-pitch wormgears has restrictions which limit the diameter, the lead range, the degree of accuracy attainable, and the kind of tooth bearing obtainable.
- 5) Special consideration must be given to top lands in fine-pitch hardened worms and wormgear-cutting tools.
- 6) Interchangeability and high production are important factors in fine-pitch worm gearing; individual matching of the worm to the gear, as often practiced with coarse-pitch precision worms, is impractical in the case of fine-pitch worm drives.

American Standard Design for Fine-pitch Worm Gearing (ANSI B6.9-1977).—This standard is intended as a design procedure for fine-pitch worms and wormgears having axes at right angles. It covers cylindrical worms with helical threads, and wormgears hobbled for fully conjugate tooth surfaces. It does not cover helical gears used as wormgears.

Hobs: The hob for producing the gear is a duplicate of the mating worm with regard to tooth profile, number of threads, and lead. The hob differs from the worm principally in that the outside diameter of the hob is larger to allow for resharpening and to provide bottom clearance in the wormgear.

Pitches: Eight standard axial pitches have been established to provide adequate coverage of the pitch range normally required: 0.030, 0.040, 0.050, 0.065, 0.080, 0.100, 0.130, and 0.160 inch.

Axial pitch is used as a basis for this design standard because: 1) Axial pitch establishes lead which is a basic dimension in the production and inspection of worms; 2) the axial pitch of the worm is equal to the circular pitch of the gear in the central plane; and 3) only one set of change gears or one master lead cam is required for a given lead, regardless of lead angle, on commonly-used worm-producing equipment.

Lead Angles: Fifteen standard lead angles have been established to provide adequate coverage: 0.5, 1, 1.5, 2, 3, 4, 5, 7, 9, 11, 14, 17, 21, 25, and 30 degrees.

This series of lead angles has been standardized to: 1) Minimize tooling; 2) permit obtaining geometric similarity between worms of different axial pitch by keeping the same lead angle; and 3) take into account the production distribution found in fine-pitch worm gearing applications.

For example, most fine-pitch worms have either one or two threads. This requires smaller increments at the low end of the lead angle series. For the less frequently used thread numbers, proportionately greater increments at the high end of the lead angle series are sufficient.

Table 1. Formulas for Proportions of American Standard Fine-pitch Worms and Wormgears ANSI B6.9-1977

<p style="text-align: center;">LETTER SYMBOLS</p> <p>P = Circular pitch of wormgear P = axial pitch of the worm, P_x, in the central plane P_x = Axial pitch of worm P_n = Normal circular pitch of worm and wormgear = P_x $\cos \lambda = P \cos \psi$ λ = Lead angle of worm ψ = Helix angle of wormgear n = Number of threads in worm N = Number of teeth in wormgear $N = nm_G$ m_G = Ratio of gearing = $N \div n$</p>	
-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	--

Item	Formula	Item	Formula
WORM DIMENSIONS		WORMGEAR DIMENSIONS^a	
Lead	$l = nP_x$	Pitch Diameter	$D = NP \div \pi = NP_x \div \pi$
Pitch Diameter	$d = l \div (\pi \tan \lambda)$	Outside Diameter	$D_o = 2C - d + 2a$
Outside Diameter	$d_o = d + 2a$	Face Width	$F_{Gmin} = 1.125 \times \sqrt{(d_o + 2c)^2 - (d_o - 4a)^2}$
Safe Minimum Length of Threaded Portion of Worm ^b	$F_W = \sqrt{D_o^2 - D^2}$		
DIMENSIONS FOR BOTH WORM AND WORMGEAR			
Addendum	$a = 0.3183P_n$	Tooth thickness	$t_n = 0.5P_n$
Whole Depth	$h_t = 0.7003P_n + 0.002$	Approximate normal pressure angle ^c	$\phi_n = 20$ degrees
Working Depth	$h_k = 0.6366P_n$	Center distance	$C = 0.5(d + D)$
Clearance	$c = h_t - h_k$		

^a Current practice for fine-pitch worm gearing does not require the use of throated blanks. This results in the much simpler blank shown in the diagram which is quite similar to that for a spur or helical gear. The slight loss in contact resulting from the use of non-throated blanks has little effect on the load-carrying capacity of fine-pitch worm gears. It is sometimes desirable to use topping hobs for producing wormgears in which the size relation between the outside and pitch diameters must be closely controlled. In such cases the blank is made slightly larger than D_o by an amount (usually from 0.010 to 0.020) depending on the pitch. Topped wormgears will appear to have a small throat which is the result of the hobbing operation. For all intents and purposes, the throating is negligible and a blank so made is not to be considered as being a throated blank.

^b This formula allows a sufficient length for fine-pitch worms.

^c As stated in the text on page 3008, the actual pressure angle will be slightly greater due to the manufacturing process.

All dimensions in inches unless otherwise indicated.

Pressure Angle of Worm: A pressure angle of 20 degrees has been selected as standard for cutters and grinding wheels used to produce worms within the scope of this Standard because it avoids objectionable undercutting regardless of lead angle.

Although the pressure angle of the cutter or grinding wheel used to produce the worm is 20 degrees, the normal pressure angle produced in the worm will actually be slightly greater, and will vary with the worm diameter, lead angle, and diameter of cutter or grinding wheel. A method for calculating the pressure angle change is given under the heading *Effect of Production Method on Worm Profile and Pressure Angle*.

Pitch Diameter Range of Worms: The minimum recommended worm pitch diameter is 0.250 inch and the maximum is 2.000 inches. Pitch diameters for all possible combinations of lead and lead angle, together with the number of threads for each lead, are given in [Table 2a](#) and [2b](#).

Tooth Form of Worm and Wormgear: The shape of the worm thread in the normal plane is defined as that which is produced by a symmetrical double-conical cutter or grinding wheel having straight elements and an included angle of 40 degrees.

Because worms and wormgears are closely related to their method of manufacture, it is impossible to specify clearly the tooth form of the wormgear without referring to the mating worm. For this reason, worm specifications should include the method of manufacture and the diameter of cutter or grinding wheel used. Similarly, for determining the shape of the generating tool, information about the method of producing the worm threads must be given to the manufacturer if the tools are to be designed correctly.

The worm profile will be a curve that departs from a straight line by varying amounts, depending on the worm diameter, lead angle, and the cutter or grinding wheel diameter. A method for calculating this deviation is given in the Standard. The tooth form of the wormgear is understood to be made fully conjugate to the mating worm thread.

Proportions of Fine-pitch Worms and Wormgears.—Hardened worms and cutting tools for wormgears should have adequate top lands. To automatically provide sufficient top lands, regardless of lead angle or axial pitch, the addendum and whole depth proportions of fine-pitch worm gearing are based on the normal circular pitch. Tooth proportions based on normal pitch for all combinations of standard axial pitches and lead angles are given in [Table 3](#). Formulas for the proportions of worms and worm gears are given in [Table 1](#).

Example 1: Determine the design of a worm and wormgear for a center distance of approximately 3 inches if the ratio is to be 10 to 1; axial pitch, 0.1600 inch; and lead angle, 30 degrees.

From [Table 2a](#) and [2b](#) it can be determined that there are eight possible worm diameters that will satisfy the given conditions of lead angle and pitch. These worms have from 3 to 10 threads.

To satisfy the 3-inch center distance requirement it is now necessary to determine which of these eight worms, together with its mating wormgear, will come closest to making up this center distance. One way of doing this is as follows:

First use the formula given below to obtain the approximate number of threads necessary. Then from the eight possible worms in [Table 2a](#) and [2b](#), choose the one whose number of threads is nearest this approximate value:

Approximate number of threads needed for required center distance =

$$\frac{2\pi \times \text{required center distance}}{P_x (\cot \lambda + m_G)}$$

Approximate number of threads =

$$\frac{2 \times 3.1416 \times 3}{0.1600 \times (1.7320 + 10)} = 10.04 \text{ threads}$$

Of the eight possible worms in [Table 2a](#) and [2b](#), the one having a number of threads nearest this value is the 10-thread worm with a pitch diameter of 0.8821 inch. Since the ratio of gearing is given as 10, N may now be computed as follows: $N = 10 \times 10 = 100$ teeth (from [Table 1](#))

Other worm and wormgear dimensions may now be calculated using the formulas given in [Table](#) or may be taken from the data presented in [Table 2a](#), [2b](#), and [3](#).

$l = 1.600$ inches (from [Table 2b](#))

$$d = 0.8821 \text{ inch (from Table 2b)}$$

$$D = 100 \times 0.1600 + 3.1416 = 5.0930 \text{ inches (from Table 1)}$$

$$C = 0.5(0.8821 + 5.0930) = 2.9876 \text{ inches (from Table 1)}$$

$$P_n = 0.1386 \text{ inch (from Table 3)}$$

$$a = 0.0441 \text{ inch (from Table 3)}$$

$$h_t = 0.0990 \text{ inch (from Table 3)}$$

$$h_k = 0.6366 \times 0.1386 = 0.0882 \text{ inch (from Table 1)}$$

$$c = 0.0990 - 0.0882 = 0.0108 \text{ inch (from Table 1)}$$

$$t_n = 0.5 \times 0.1386 = 0.0693 \text{ inch (from Table 1)}$$

$$d_o = 0.8821 + (2 \times 0.0441) = 0.9703 \text{ inch (from Table 1)}$$

$$D_o = (2 \times 2.9876) - 0.8821 + (2 \times 0.0441) = 5.1813 \text{ (from Table 1)}$$

$$F_G = 1.125 \sqrt{(0.9703 + 2 \times 0.0108)^2 - (0.9703 - 4 \times 0.0441)^2} = 0.6689 \text{ inch}$$

$$F_W = \sqrt{5.1813^2 - 5.0930^2} = 0.9525 \text{ inch}$$

Example 2: Determine the design of a worm and wormgear for a center distance of approximately 0.550 inch if the ratio is to be 50 to 1 and the axial pitch is to be 0.050 inch.

Assume that $n = 1$ (since most fine-pitch worms have either one or two threads). The lead of the worm will then be $nP_x = 1 \times 0.050 = 0.050$ inch. From Table 2a and 2b it can be determined that there are six possible lead angles and corresponding worm diameters that will satisfy this lead. The approximate lead angle required to meet the conditions of the example can be computed from the following formula:

$$\text{Cotangent of approx. lead angle} = \frac{2\pi \times \text{approximate center distance required}}{\text{assumed number of threads} \times \text{axial pitch}} - m_G$$

Using letter symbols, this formula becomes:

Of the six possible worms in Table 2a and 2b, the one with the 3-degree lead angle is closest to the calculated $2^\circ 59'$ lead angle. This worm, which has a pitch diameter of 0.3037 inch, is therefore selected.

The remaining worm and wormgear dimensions may now be determined from the data in Table 2a, 2b and 3 and by computation using the formulas given in Table 1.

$$N = 50 \times 1 = 50 \text{ teeth (from Table 1)}$$

$$d = 0.3037 \text{ inch (from Table 2b)}$$

$$D = 50 \times 0.050 \div 3.1416 = 0.7958 \text{ inch (from Table 1)}$$

$$C = 0.5(0.3037 + 0.7958) = 0.5498 \text{ inch (from Table 1)}$$

$$P_n = 0.0499 \text{ inch (from Table 3)}$$

$$a = 0.0159 \text{ inch (from Table 3)}$$

$$h_t = 0.0370 \text{ inch (from Table 3)}$$

$$h_k = 0.6366 \times 0.0499 = 0.0318 \text{ inch (from Table 1)}$$

$$c = 0.0370 - 0.0318 = 0.0052 \text{ inch (from Table 1)}$$

$$t_n = 0.5 \times 0.0499 = 0.0250 \text{ inch (from Table 1)}$$

$$d_o = 0.3037 + (2 \times 0.0159) = 0.3355 \text{ inch (from Table 1)}$$

$$D_o = (2 \times 0.5498) - 0.3037 + (2 \times 0.0159) = 5.1813 \text{ (from Table 1)}$$

$$F_{Gmin} = 1.125 \sqrt{(0.3355 + 2 \times 0.0052)^2 - (0.3355 - 4 \times 0.0159)^2} = 0.2405 \text{ inch}$$

$$F_W = \sqrt{0.8277^2 - 0.7958^2} = 0.2276 \text{ inch}$$

Effect of Production Method on Worm Profile and Pressure Angle.—In worm gearing, tooth bearing is usually used as the means of judging tooth profile accuracy since direct profile measurements on fine-pitch worms or wormgears is not practical. According to AGMA 370.01, Design Manual for Fine-Pitch Gearing, a minimum of 50 per cent initial area of contact is suitable for most fine-pitch worm gearing, although in some cases, such as when the load fluctuates widely, a more restricted initial area of contact may be desirable.

Except where single-pointed lathe tools, end mills, or cutters of special shape are used in the manufacture of worms, the pressure angle and profile produced by the cutter are different from those of the cutter itself. The amounts of these differences depend on several factors, namely, diameter and lead angle of the worm, thickness and depth of the worm thread, and diameter of the cutter or grinding wheel. The accompanying diagram shows the curvature and pressure angle effects produced in the worm by cutters and grinding wheels, and how the amount of variation in worm profile and pressure angle is influenced by the diameter of the cutting tool used.

Effect of Diameter of Cutting on Profile and Pressure Angle of Worms

Calculating Worm Deviations and Pressure Angle Changes: Included in American Standard ANSI B6.9-1977 is an extensive tabulation of profile deviations and pressure angle changes produced by cutters and grinding wheels of 2-inch and 20-inch diameters. These diameters represent the limits of the range commonly used, and the data given are useful in specifying worm profile tolerances. The data also aid in the selection of the method to be used in producing the worm and in specifying the hobs for wormgears. The formulas used to compute the data in the Standard are given here in slightly modified form, and may be used to calculate the profile deviations and pressure angle changes produced in the worm by cutters or grinding wheels.

$$\rho_{ni} = \frac{r \sin \phi_n}{(\sin \lambda)^2} \text{ inches} \tag{1}$$

$$\rho_n = \rho_{ni} + \frac{r \rho_{ni}}{R(\cos \lambda)^2} \text{ inches} \tag{2}$$

$$\Delta \phi = \frac{5400r(\sin \lambda)^3}{n(R(\cos \lambda)^2 + r)} \text{ minutes} \tag{3}$$

$$q = a \sec \phi_n \text{ inches} \quad (4)$$

$$y = \frac{q^2}{2\rho_n} \text{ inches} \quad (5)$$

$$s = 0.000582q\Delta\phi \text{ inches} \quad (6)$$

$$\Delta y = y_w - y_c \text{ inches} \quad (7)$$

$$\Delta s = s_c - s_w \text{ inches} \quad (8)$$

In these formulas,

ρ_{ni} = radius of curvature of normal thread profile for involute thread;

r = pitch radius of worm;

Φ_n = normal pressure angle of cutter or grinding wheel;

λ = lead angle of worm;

ρ_n = radius of curvature of normal thread profile;

R = radius of cutter or grinding wheel;

$\Delta\Phi$ = difference between the normal pressure angle of the thread and the normal pressure angle of the cutter or grinding wheel in minutes (see diagram). Subscripts c and w are used to denote the cutter and grinding wheel diameters, respectively;

n = number of threads in worm;

a = addendum of worm;

q = slant height of worm addendum;

y = amount normal worm profile departs from a straight side (see diagram). Subscripts c and w are used to denote the cutter and grinding wheel diameters, respectively;

s = effect along slant height of worm thread caused by change in pressure angle $\Delta\Phi$

Δy = difference in y values of two cutters or grinding wheels of different diameter (see diagram);

Δs = effect of $\Delta\Phi_c - \Delta\Phi_w$ along slant height of thread (see diagram).

Example 3: Assuming the worm dimensions are the same as in [Example 1](#), determine the corrections for two worms, one milled by a 2-inch diameter cutter, the other ground by a 20-inch diameter wheel, both to be assembled with identical wormgears.

To make identical worms when using a 2-inch cutter and a 20-inch wheel, the pressure angle of either the cutter or the wheel must be corrected by an amount corresponding to Δs and the profile of the cutter or wheel must be a curve which departs from a straight line by an amount Δy . The calculations are as follows:

For the 2-inch diameter cutter, using [Formula \(1\)](#) to [\(6\)](#),

$$\rho_{ni} = \frac{0.4410 \times 0.3420}{0.5000^2} = 0.6033 \text{ inch} \quad (1)$$

$$\rho_n = 0.6033 + \frac{0.4410 \times 0.6033}{1 \times 0.8660^2} = 0.9581 \text{ inch} \quad (2)$$

$$\Delta\phi_c = \frac{5400 \times 0.4410 \times 0.5000^3}{10(1 \times 0.8660^2 + 0.4410)} = 24.99 \text{ inches} \quad (3)$$

$$q = 0.0441 \times 1.0642 = 0.0469 \text{ inch} \quad (4)$$

WORM GEARING

$$y_c = \frac{0.0469^2}{2 \times 0.6387} = 0.00172 \text{ inches} \quad (5)$$

$$s_c = 0.000582 \times 0.0469 \times 24.99 = 0.000682 \text{ inch} \quad (6)$$

For the 20-inch diameter wheel, using [Formula \(1\)](#) to [\(6\)](#)

$$\rho_{ni} = \frac{0.4410 \times 0.3420}{0.5000^2} = 0.6033 \text{ inch} \quad (1)$$

$$\rho_n = 0.6033 + \frac{0.4410 \times 0.6033}{10 \times 0.8660^2} = 0.6387 \text{ inch} \quad (2)$$

$$\Delta\phi_w = \frac{5400 \times 0.4410 \times 0.5000^3}{10(10 \times 0.8660^2 + 0.4410)} = 3.749 \text{ inches} \quad (3)$$

$$q = 0.0441 \times 1.0642 = 0.0469 \text{ inch} \quad (4)$$

$$y_w = \frac{0.0469^2}{2 \times 0.6387} = 0.00172 \text{ inches} \quad (5)$$

$$s_w = 0.000582 \times 0.0469 \times 3.749 = 0.000102 \text{ inch} \quad (6)$$

Applying [Formula \(7\)](#) to [\(8\)](#):

$$\Delta y = 0.00172 - 0.00115 = 0.00057 \text{ inch} \quad (7)$$

$$\Delta s = 0.000682 - 0.000102 = 0.000580 \text{ inch} \quad (8)$$

Therefore the pressure angle of either the cutter or the wheel must be corrected by an amount corresponding to a Δs of 0.00580 inch and the profile of the cutter or wheel must be a curve which departs from a straight line by 0.00057 inch.

Industrial Worm Gearing.—The primary considerations in industrial worm gearing are usually:

- 1) To transmit power efficiently;
- 2) to transmit power at a considerable reduction in velocity; and
- 3) to provide a considerable "mechanical advantage" when a given applied force must overcome a comparatively high resisting force.

Worm gearing for use in such applications is usually of relatively coarse pitch. The notation below is used in the formulas on the following pages.

<i>a</i>	addendum, worm thread	<i>m</i>	module = 0.3183 × axial pitch
<i>A</i>	addendum, wormgear tooth	<i>N</i>	revolutions per minute of wormgear
<i>B</i>	dedendum, wormgear tooth	<i>n</i>	revolutions per minute of worm
<i>b</i>	dedendum, worm thread	<i>P</i>	axial pitch of worm and circular pitch of wormgear
<i>C</i>	center distance (Fig. 1, p. 1928)	<i>P_n</i>	normal pitch of worm
<i>c</i>	clearance	<i>Q</i>	arc length of wormgear tooth measured along root
<i>D</i>	pitch diameter of wormgear		ratio of worm gearing = No. of wormgear teeth ÷ No. of worm threads.
<i>d</i>	pitch diameter of worm	<i>S_c</i>	surface stress factor (Table 4)
<i>d_o</i>	outside diameter of worm	<i>S_b</i>	bending stress factors, lbs. per sq. in. (Table 4)
<i>D_o</i>	outside or over-all diameter of wormgear	<i>T</i>	number of teeth on wormgear

D_t	throat diameter of wormgear	t	number of threads or "starts" and on worm-2 for double thread, 3 for triple thread, 4 for quadruple thread, etc.
E	efficiency of worm gearing, per cent	U	radius of wormgear throat (Fig. 11)
F	nominal face width of wormgear rim	V	rubbing speed of worm in feet per minute
F_e	effective face width (Fig. 11, p. 1928)	W	whole tooth depth (worm and-wormgear)
f	coefficient of friction	X_{cp} and X_{cw}	speed factor when load rating is limited by wear (Fig. 11)
G	length of worm threaded section	X_{bp} and X_{bw}	speed factor when load rating is limited by strength (Table 5)
H	horsepower rating	ϕ	angle of friction ($\tan \phi =$ coefficient of friction)
L	lead of worm thread = pitch \times number of threads or "starts"		
L_a	lead angle of worm = helix angle measured from a plane perpendicular to worm axis		
M	torque applied to wormgear, pound inches		

Materials for Worm Gearing.—Worm gearing, especially for power transmission, should have steel worms and phosphor bronze wormgears. This combination is used extensively. The worms should be hardened and ground to obtain accuracy and a smooth finish.

The phosphor bronze wormgears should contain from 10 to 12 per cent of tin. The S.A.E. phosphor gear bronze (No. 65) contains 88–90% copper, 10–12% tin, 0.50% lead, 0.50% zinc (but with a maximum total lead, zinc and nickel content of 1.0 percent), phosphorous 0.10–0.30%, aluminum 0.005%. The S.A.E. nickel phosphor gear bronze (No. 65 + Ni) contains 87% copper, 11% tin, 2% nickel and 0.2% phosphorous.

Single-thread Worms.—The ratio of the worm speed to the wormgear speed may range from 1.5 or even less up to 100 or more. Worm gearing having high ratios are not very efficient as transmitters of power; nevertheless high as well as low ratios often are required. Since the ratio equals the number of wormgear teeth divided by the number of threads or "starts" on the worm, single-thread worms are used to obtain a high ratio. As a general rule, a ratio of 50 is about the maximum recommended for a single worm and wormgear combination, although ratios up to 100 or higher are possible. When a high ratio is required, it may be preferable to use, in combination, two sets of worm gearing of the multi-thread type in preference to one set of the single-thread type in order to obtain the same total reduction and a higher combined efficiency.

Single-thread worms are comparatively inefficient because of the effect of the low lead angle; consequently, single-thread worms are not used when the primary purpose is to transmit power as efficiently as possible but they may be employed either when a large speed reduction with one set of gearing is necessary, or possibly as a means of adjustment, especially if "mechanical advantage" or self-locking are important factors.

Multi-thread Worms.—When worm gearing is designed primarily for transmitting power efficiently, the lead angle of the worm should be as high as is consistent with other requirements and preferably between, say, 25 or 30 and 45 degrees. This means that the worm must be multi-threaded. To obtain a given ratio, some number of wormgear teeth divided by some number of worm threads must equal the ratio. Thus, if the ratio is 6, combinations such as the following might be used:

$$\frac{24}{4}, \frac{30}{5}, \frac{36}{6}, \frac{42}{7}$$

The numerators represent the number of wormgear teeth and the denominators, the number of worm threads or "starts." The number of wormgear teeth may not be an exact multiple of the number of threads on a multi-thread worm in order to obtain a "hunting tooth" action.

Number of Threads or "Starts" on Worm: The number of threads on the worm ordinarily varies from one to six or eight, depending upon the ratio of the gearing. As the ratio is increased, the number of worm threads is reduced, as a general rule. In some cases, however, the higher of two ratios may also have a larger number of threads. For example, a ratio of $6\frac{1}{5}$ would have 5 threads whereas a ratio of $6\frac{5}{6}$ would have 6 threads. Whenever the ratio is fractional, the number of threads on the worm equals the denominator of the fractional part of the ratio.

Table 4. Rules and Formulas for Worm Gearing

No.	To Find	Rule	Formula
1	Addendum	Addendum may be affected by lead angle. See paragraph, Addendum and Dedendum.	
2	Center Distance	Add pitch diameter of wormgear to pitch diameter of worm, and divide sum by 2	$C = \frac{D+d}{2}$
3		Divide number of worm threads by tangent lead angle, add number of wormgear teeth and multiply sum by quotient obtained by dividing pitch by 6.2832	$C = \frac{P}{6.2832} \left(\frac{t}{\tan L_a} + T \right)$
4	Dedendum	Dedendum may be affected by lead angle. See paragraph, Addendum and Dedendum	
5	Clearance	British Standard-multiply cosine lead angle by 0.2 times module.	$c = 0.2m \cos L_a$
6	Face width Wormgear	For single and double thread worms, multiply pitch by 2.38 and add 0.25. (shell type worm.)	$F = 2.38P + 0.25$
7		For triple and quadruple thread multiply pitch by 2.15 and add 0.2. (shell type)	$F = 2.15P + 0.20$
8		When worm threads are integral with shaft, face width of wormgear may be equal $C^{0.875}$ divided by 3.	$F = \frac{C^{0.875}}{3}$
9	Lead of Worm thread	Multiply pitch by number of worm threads or "starts"	$L = 1P$
10		Multiply pitch circumference of worm by tangent of lead angle.	$L = \pi d \times \tan L_a$
11		Divide pitch circumference of wormgear by ratio.	$L = \pi D \div R$
12	Lead Angle, Worm	Divide lead by pitch circumference of worm; quotient is tangent of lead angle.	$\tan L_a = \frac{L}{3.1416d}$
13	Outside Diam., Worm	Add to pitch diameter twice the addendum. see paragraph, pitch diameter of worm; also Addendum and Dedendum.	$d_0 = d + 2a$
14	Outside Diam., Wormgear	For outside or over-all diameter of wormgear, see paragraph, outside diameter of wormgear.	

Table 4. (Continued) Rules and Formulas for Worm Gearing

No.	To Find	Rule	Formula
15	Pitch of Worm and Wormgear	Divide lead by number of threads or "starts" on worm = axial pitch of worm and circular pitch of wormgear.	$P = \frac{L}{t}$
16		Subtract the worm pitch diameter from twice the center distance. Multiply by 3.1416 and divide by number of wormgear teeth.	$P = \frac{(2C - d)3.1416}{T}$
17	Pitch of Worm, Normal	Multiply axial pitch by cosine of lead angle to find normal pitch.	$P_n = P \times \cos L_a$
18	Pitch Diameter, Worm	Subtract pitch diameter of worm gear from twice the center distance.	$d = 2C - D$
19		Subtract twice the addendum from outside diameter. See Addendum and Dedendum.	$D = d_0 - 2a$
20		Multiply lead by cotangent lead angle and divide product by 3.1416	$d = \frac{L \times \cot L_a}{3.1416}$
21	Pitch Diameter, Wormgear	Subtract pitch diameter of worm from twice the center distance.	$D = 2C - d$
22		Multiply number of wormgear teeth by axial pitch of worm and divide product by 3.1416.	$D = \frac{TP}{3.1416}$
23	Radius of Rim Corner, Wormgear	Multiply pitch by 0.25	Radius = $0.25P$
24		British Standard: Radius = $0.5 \times$ module.	Radius = $0.50m$
25	Ratio	Divide number of wormgear teeth by number of worm threads.	$R = T \div t$
26	Rubbing speed, ft. per minute	Divide wormgear pitch diameter by ratio; square quotient and add to square of worm pitch diameter; multiply square root of this sum by $0.262 \times$ R.P.M. of worm.	$V = 0.262n \sqrt{d^2 + \left(\frac{D}{4}\right)^2}$
27		Multiply $0.262 \times$ Pitch diameter of worm by worm R.P.M. of worm; then multiply product by secant of lead angle.	$V = 0.262dn \times \sec L_a$
28	Throat Diameter Wormgear	Add twice the addendum to pitch diameter. See paragraph, Addendum and Dedendum	$D_t = D + 2A$
29	Throat Radius Wormgear	Subtract twice the addendum from outside radius of worm.	$U = \frac{d_0}{2} - 2a$
30	Total Depth	Whole depth equals addendum + Dedendum. See paragraph, Addendum and Dedendum	$W = a + b$ or $A + B$
31	Worm Thread Length	Multiply the number of wormgear teeth by 0.02, add 4.5 and multiply sum by pitch.	$G = P(4.5 + 0.02T)$
32		British Standard subtract square of wormgear pitch diameter from square of outside diameter and extract square root of remainder.	$G = \sqrt{D_0^2 - D^2}$

Ratio for Obtaining "Hunting Tooth" Action.—In designing wormgears having multi-thread worms, it is common practice to select a number of wormgear teeth that is not an exact multiple of the number of worm threads. To illustrate, if the desired ratio is about 5 or 6, the actual ratio might be $5\frac{1}{6}$, $5\frac{5}{6}$, $5\frac{2}{3}$, $6\frac{1}{5}$, etc., so that combinations such as $\frac{31}{6}$, $\frac{35}{6}$, $\frac{37}{4}$ or $\frac{37}{5}$ would be obtained. Since the number of wormgear teeth and number of worm threads do not have a common divisor, the threads of the worm will mesh with all of the wormgear teeth in succession, thus obtaining a "hunting tooth" or self-indexing action. This progressive change will also occur during the wormgear hobbing operation, and its primary purpose is to produce more accurate wormgears by uniformly distributing among all of the teeth, any slight errors which might exist in the hob teeth. Another object is to improve the

“running-in” action between the hardened and ground worm and the phosphor bronze wormgear, but in order to obtain this advantage, the threads on the worm must be accurately or uniformly spaced by precise indexing. With a “hunting tooth ratio,” if the thread spacing of a multi-thread worm is inaccurate, load distribution on the threads will be unequal and some threads might not even make contact with the wormgear teeth. For this reason, if the indexing is inaccurate, it is preferable to avoid a hunting tooth ratio, but in that case, if the gearing is disassembled, the same worm and wormgear teeth should be mated when reassembled.

Fig. 11.

Pitch Diameter of Worm.—The worm must be strong enough to transmit its maximum load without excessive deflection but the diameter should be as small as is consistent with the necessary strength in order to minimize the rubbing speed. It is impracticable to give a rule or formula that is generally applicable, but the following empirical rules are based upon actual practice and may prove useful as a general guide. They apply to casehardened alloy steel worms which are integral with the shaft.

For ratios of 5, 6, or 7, the pitch diameter ranges approximately from 0.38 C when center distance C is 4 inches to 0.33 C when C is 20 inches.

For ratios of 8, 9, 10, the pitch diameter ranges approximately from 0.38 C when center distance C is 4 inches to 0.25 C when C is 30 inches.

For ratios of 10 to 20, the pitch diameter ranges approximately from 0.37 C when center distance C is 4 inches to 0.24 C when C is 30 inches.

For ratios of 20 to 40, the pitch diameter ranges approximately from 0.36 C when center distance C is 4 inches to 0.23 C when C is 30 inches.

According to another empirical formula pitch diameter $d = C^{0.75} + 2.2$.

Addendum and Dedendum.—The following A.G.M.A. formulas are applicable to industrial worm gearing. For single and double thread worms, addendum $a = 0.318 P$ and whole depth $W = 0.686 P$; for triple and quadruple threads, addendum $a = 0.286 P$ and whole depth $W = 0.623 P$.

According to the British standard, $a = \text{module } m = 0.3183 P$; $b = m(2.2 \cos L_a - 1)$; $A = m(2.2 \cos L_a - 1)$; $B = m(1 + 0.2 \cos L_a)$.

Outside Diameter of Wormgear.—Practice varies somewhat in determining the outside or over-all diameter of the wormgear, as indicated by the following formulas. For usual rim shape, see Fig. 11.

- 1) For lead angles up to about 15 or 20 degrees, $D_o = D + (3 \times 0.3183 P)$
- 2) For lead angles over 20 degrees, $D_o = D + (3 \times 0.3183 P \times \cos L_a)$
- 3) For single and double thread, $D_o = D_t + 0.4775 P$
- 4) For triple and quadruple thread, $D_o = D_t + 0.3183 P$

Pressure Angles.—The pressure angle (one-half the included thread angle) ranges from $14\frac{1}{2}$ to 30 degrees. While the practice varies somewhat, the following relationship between lead angle and pressure angle may be used as a general guide.

For lead angles up to about 10 or 12 degrees, pressure angle = $14\frac{1}{2}$ degrees.

For lead angles from 10 or 12 to about 20 or 25 degrees, pressure angle = 20 degrees.

For lead angles from 25 to about 35 degrees, pressure angle = 25 degrees.

For lead angles over 35 degrees, pressure angle = 30 degrees.

In the British Standard specifications, the recommended thread form has a normal pressure angle of 20 degrees.

Designing Worm Gearing Relative to Center Distance and Ratio.—In designing worm gearing, three general cases or types of problems may be encountered in establishing the proportions of the worm and wormgear.

When Center Distance is Fixed and Ratio may be Varied: The ratio in this case is nominal and may be varied somewhat to meet other conditions. Assume that the required center distance is 6 inches, the desired ratio is about 7, and the pitch of the worm and wormgears is to be approximately 1 inch. Combinations of wormgears and worms such as the following might be used in this case:

$$\frac{28}{4}, \frac{35}{5}, \frac{42}{6}, \frac{56}{8}, \text{ etc.}$$

Suppose we select the $\frac{28}{4}$ combination for trial but change the number of worm-gear teeth from 28 to 29 to obtain a self-indexing or "hunting tooth" action. The ratio now equals $\frac{29}{4}$ or 7.25. Then, for trial purposes

$$\text{Pitch diameter } D \text{ of wormgear} = \frac{T \times P}{\pi} = \frac{29 \times 1}{3.1416} = 9.231 \text{ inches}$$

$$\text{Pitch diameter } d \text{ of wormgear} = 2C - D = 2 \times 6 - 9.231 = 2.769 \text{ inches}$$

Assume that experience, tests, or calculations show that a worm of smaller diameter will have the necessary bending and torsional strength and that a pitch of 1.0625 will be satisfactory. Then the pitch diameter of the worm will be decreased to 2.192 inches and the pitch diameter of the wormgear will be increased to 9.808 inches. A check of the lead-angle will show that it equals $31^\circ 41'$ which is conducive to high efficiency.

When Ratio is Fixed and Center Distance may be Varied: Assume that the required ratio is $7\frac{1}{4}$ and that the center distance may be any value consistent with approved designing practice. This ratio may be obtained with a number of different worm and wormgear sizes. For example, in a series of commercial wormgears, the following combinations are employed for gearing having a ratio of $7\frac{1}{4}$ with center distances varying from 4 to 8.25 inches. The number of worm threads is 4 and the number of teeth on the wormgear is 29 in all cases.

$$\text{When } C = 4 \text{ inches, } d = 1.654; D = 6.346; P = 0.6875; L_a = 27^\circ 54'$$

When $C = 5$ inches, $d = 1.923$; $D = 8.077$; $P = 0.875$; $L_a = 30^\circ 5'$

When $C = 6$ inches, $d = 2.192$; $D = 9.808$; $P = 1.0625$; $L_a = 31^\circ 41'$

When $C = 7$ inches, $d = 2.461$; $D = 11.539$; $P = 1.25$; $L_a = 32^\circ 53'$

When $C = 8.25$ inches, $d = 2.942$; $D = 13.558$; $P = 1.4687$; $L_a = 32^\circ 27'$

The horsepower rating increases considerably as the proportions of the worm gearing increase; hence if the gears are intended primarily for power transmission, the general proportions must be selected with reference to the power-transmitting capacity, and, usually the smallest and most compact design that will give satisfactory performance should be selected. The power capacity of the transmission, however, does not depend solely upon the proportions of the worm and wormgear. For example, the quality and viscosity of the lubricant is an important factor. The load transmitting capacity of the lubricant may also be increased decidedly when excessive temperature rises are prevented by special means such as forced air cooling. (See "Water and Forced-Air Cooling.")

When Both Ratio and Center Distance are Fixed: When both ratio and center distance are fixed, the problem usually is to obtain the best proportions of worm and wormgear conforming to these fixed values.

Example: The required ratio is 6 (6 to 1) and the center distance is fixed at 3.600 inches. Assume that experience or tests show that an axial pitch of 0.50 inch will meet strength requirements. If normal pitch P_n is given, change to axial pitch ($P = P_n \div \cos L_a$). With a

ratio of 6, some of the combinations for trial are: $\frac{30}{5}, \frac{36}{6}, \frac{42}{7}$

Trial calculations will show that the $\frac{36}{6}$ combination gives the best proportions of worm and wheel for the center distance and pitch specified. Thus

$$D = \frac{TP}{\pi} = \frac{36 \times 0.5}{3.1416} = 5.729; \quad d = 2C - D = 2 \times 3.6 - 5.729 = 1.471$$

The lead angle is about 33 degrees. The effect of lead angle on efficiency is dealt with in a following paragraph. The total obtained by adding the number of worm-gear teeth to the number of worm threads, equals $36 + 6 = 42$ (a total of 40 is a desirable minimum). With the $\frac{42}{7}$ combination of the same pitch, the worm would be too small (0.516 inch); and with the $\frac{30}{5}$ combination it would be too large (2.426 inches). The present trend in gear designing practice is to use finer pitches than in the past. In the case of worm gearing, the pitch may, in certain instances, be changed somewhat either to permit cutting with available equipment or to improve the proportions of worm and wheel.

When Ratio, Pitch and Lead Angle are Fixed: Assume that $R = 10$, axial pitch $P = 0.16$ inch, $L_a = 30$ degrees and $C = 3$ inches, approximately.

The first step is to determine for the given ratio, pitch and lead angle, the number of worm threads t which will give a center distance nearest 3 inches.

The whole number nearest 10.04, or 10, is the required number of worm threads; hence number of teeth on wormgear equals $R \times 10 = 100$

$$d = (L \cot L_a) \div \pi = (10 \times 0.16 \times 1.732) \div \pi = 0.8821 \text{ inches}$$

$$D = (TP) \div \pi = (100 \times 0.16) \div \pi = 5.0929 \text{ inches}$$

$$C = (D + d) \div 2 = (5.0929 + 0.8821) \div 2 = 2.9875 \text{ inches}$$

Efficiency of Worm Gearing.—The efficiency at a given speed, depends upon the worm lead angle, the workmanship, the lubrication, and the general design of the transmission. When worm gearing consists of a hardened and ground worm running with an accurately hobbled wormgear properly lubricated, the efficiency depends chiefly upon the lead angle

and coefficient of friction between the worm and worm-gear. In the lower range of lead angles, the efficiency increases considerably as the lead angle increases, as shown by Table 5 and . This increase in efficiency remains practically constant for lead angles between 30 and 45 degrees. Several formulas for obtaining efficiency percentage follow:
With worm driving:

$$E = 100 - \frac{R}{2} \text{ (empirical rule); } E = \frac{100 \times \tan L_a}{\tan(L_a + \phi)} ; E = \frac{100 \times L}{L + f\pi d}$$

With wormgear driving

$$E = 100 - 2R \text{ (empirical rule); } E = \frac{100 \times \tan(L_a - \phi)}{\tan L_a}$$

The efficiencies obtained by these formulas and other modifications of them differ somewhat and do not take into account bearing and oil-churning losses. The efficiency may be improved somewhat after the "running in" period.

Table 5. Efficiency of Worm Gearing for Different Lead Angles and Frictional Coefficients

Coefficient of friction	Lead angle of worm in degrees								
	5 Deg.	10 Deg.	15 Deg.	20 Deg.	25 Deg.	30 Deg.	35 Deg.	40 Deg.	45 Deg.

^a These values for different rubbing speeds are based upon the use of phosphor bronze wormgears with case-hardened ground and polished steel worms lubricated with mineral oil.

Self-locking or Irreversible Worm Gearing.—Neglecting friction in the bearings, worm gearing is irreversible when the efficiency is zero or negative, the lead angle being equal to or less than the angle ϕ of friction ($\tan \phi =$ coefficient of friction). When worm gearing is self-locking or irreversible, this means that the worm-gear cannot drive the worm. Since the angle of friction changes rapidly with the rubbing speed, and the static angle of friction may be reduced by external vibration, it is usually impracticable to design irreversible worm gearing with any security. If irreversibility is desired, it is recommended that some form of brake be employed.

Worm Gearing Operating Temperatures.—The load capacity of a worm gearing lubricant at operating temperature is an important factor in establishing the continuous power-transmitting capacity of the gearing. If the churning or turbulence of the oil generates excessive heat, the viscosity of the lubricant may be reduced below its load-supporting capacity. The temperature measured in the oil sump should not, as a rule, exceed 180 to 200 degrees F. or rise more than 120 to 140 degrees F. above a surrounding air temperature of 60 degrees F. In rear axle motor vehicle transmissions, the maximum operating temperature may be somewhat higher than the figures given and usually is limited to about 220 degrees F.

Thermal Rating.—In some cases, especially when the worm speed is comparatively high, the horsepower capacity of worm gearing should be based upon its thermal rating instead of the mechanical rating. To illustrate, worm gearing may have a thermal rating of, say, 60 H.P., and mechanical ratings which are considerably higher than 60 for the higher

speed ranges. This means that the gearing is capable of transmitting more than 60 H.P. so far as wear and strength are concerned but not without overheating; hence, in this case a rating of 60 should be considered maximum. Of course, if the power to be transmitted is less than the thermal rating for a given ratio, then the thermal rating may be ignored.

Water and Forced-Air Cooling.—One method of increasing the thermal rating of a speed-reducing unit of the worm gearing type, is by installing a water-cooling coil through which water is circulated to prevent an excessive rise of the oil temperature. According to one manufacturer, the thermal rating may be increased as much as 35 per cent in this manner. Much larger increases have been obtained by means of a forced air cooling system incorporated in the design of the speed-reducing unit. A fan which is mounted on the worm shaft draws air through a double walled housing, thus maintaining a comparatively low oil bath temperature. A fan cooling system makes it possible to transmit a given amount of power through a worm-gearing unit that is much smaller than one not equipped with a fan.

Double-enveloping Worm Gearing.—Contact between the worm and wormgear of the conventional type of worm gearing is theoretically a line contact; however, due to deflection of the materials under load, the line is increased to a narrow band or contact zone. In attempting to produce a double-enveloping type of worm gearing (with the worm curved longitudinally to fit the curvature of the gear as shown by illustration), the problem primarily was that of generating the worm and worm-gear in such a manner as to obtain area contact between the engaging teeth. A practical method of obtaining such contact was developed by Samuel I. Cone at the Norfolk Navy Yard, and this is known as "Cone-Drive" worm gearing. The Cone generating method makes it possible to cut the worm and wormgear without any interference which would alter the required tooth form. The larger tooth bearing area and multiple tooth contact obtained with this type of worm gearing, increases the load-carrying or horsepower capacity so that as compared with a conventional worm drive a double-enveloping worm drive may be considerably smaller in size. [Table 6](#), which is intended as a general guide, gives input horsepower ratings for Cone-Drive worm gearing for various center distances of from 2 to 12 inches. These ratings are based on AGMA specifications 341, 441, and 641. They allow for starting and momentary peak overloads of up to 300 per cent of the values shown in [Table 5](#) using a service factor of 1. Factors for various types of service are given in [Table 7](#). To obtain the mechanical horsepower rating required, multiply the appropriate rating given in [Table 6](#) by the service factor taken from [Table 7](#).

*Horsepower ratings are for Class 1 service, using splash lubrication, except for that shown in italics, for which force feed lubrication is required. Other ratios and center distances are available.

Table 7. Service Factors for Cone-Drive Worm Gearing

Hours/Day	Uniform Motion	Moderate Shock	Heavy Shock	Extreme Shock
0.5	0.6	0.8	0.9	1.1
1	0.7	0.9	1	1.2
2	0.9	1	1.2	1.3
10	1	1.2	1.3	1.5
24	1.2	1.3	1.5	1.75

Thermal Horsepower Rating: When the operation is to be continuous, consideration must be given to the possibility of overheating. For this possibility, the thermal horsepower rating given in Ex-Cell-O Corporation, Cone Drive Operations catalog must be checked. The thermal rating defines the maximum horsepower which can be transmitted continuously (30 minutes or longer). This is based on an oil sump temperature rise of 100 deg. F above the ambient temperature. This rise must not exceed 200 deg. F. If the thermal rating is lower than the mechanical rating, the unit must be selected on the basis of the thermal rating.

Type of Drive Connection: If either input or output shaft is connected to driver or driven mechanism by other than a direct shaft coupling, the overhead load requirement (chain pull) must be calculated by dividing the torque demand by the pitch radius of the sprocket, sheave, spur gear, or helical gear used. The result is multiplied by the overhung load factor which is: for a chain sprocket, 1.00; for spur or helical gearing, 1.25; for a V-belt sheave, 1.50; and for a flat belt sheave, 2.50. As modified by the applicable overhung load factor, this load may not exceed the overhung load rating given in the company catalog.

Locking Considerations: It is a common misconception that all worm gears are self-locking or non-overhauling. Actually, wormgear ratios up 15 to 1 will overhaul quite freely. Ratios from 20:1 to 40:1 can generally be considered as overhauling with difficulty, particularly from rest. Ratios above 40:1 may or may not overhaul depending on the loading, lubrication, and amount of vibration present. Therefore it is not acceptable to rely on a wormgear to prevent movement in a system. Whenever a load must be stopped or held in place, a positive mechanical device must be incorporated into the system to prevent rotation of the gearset.

Backdriving or Overhauling: Applications such as wheel drives that require a brake on the motor or input shaft to decelerate a high inertial load require special attention to brake selection. Wherever possible, these applications should utilize freely overhauling ratios (15:1 or less). If higher ratios are used with a brake, the gearset can, under certain conditions, lockup during deceleration and impose severe shock loading on the reducer and driven equipment.

Stairstepping: Self-locking ratios (generally 40:1 and higher) are susceptible to the phenomenon of "stair stepping" when back driving or overhauling. This erratic rotation of the gear set occasionally occurs when the gear set is back driven at worm speeds less than the theoretical lockup speed of the gear set and can be amplified by the rest of the drive train creating a very undesirable operating condition. "Stair stepping" can occur on drives where there is a high inertial load at the output shaft.

Backlash: Defined as the amount of movement at the pitch line of the gear with the worm locked and the gear set on exact center distance, backlash normally ranges from 0.003 to 0.008 inch for a 2-inch center distance set up to 0.012 to 0.020 inch for a 12-inch center distance set. When the gear set is assembled into a machine or reducer, the assembled backlash may fall outside these limits depending upon worm and gear bearing looseness and the actual center distance used.

Lubrication: Lubricating oils for use in double-enveloping worm drive units should be well refined petroleum oils of high quality. They should not be corrosive to gears or bear-

ings and they must be neutral in reaction and free from grit or abrasives. They should have good defoaming properties and good resistance to oxidation. For worm gears, add up to 3 to 10 per cent of acid less tallow or similar animal fat.

The oil bath temperature should not exceed 200 degrees F. Where worm speed exceeds 3600 revolutions per minute, or 2000 feet per minute rubbing speed, a force feed lubrication may be required. Auxiliary cooling by forced air, water coils in sump, or an oil heat exchanger may be provided in a unit where mechanical horsepower rating is in excess of the thermal rating, if full advantage of mechanical capacity is to be realized. The rubbing speed (V), in feet per minute, may be calculated from the formula: $V = 0.262 \times \text{worm thread diameter in inches} \times \text{worm RPM} \div \cos \text{lead angle}$.

Worm Thread Cutting.—Worm threads are cut either by using some form of thread-cutting lathe and a single-point tool, by using a thread milling machine and a disk type of cutter, or by using a gear-hobbing machine. Single-thread worms usually have an included angle of 29 degrees. Many worm gears used at the present time, especially for power transmission, have thread angles larger than 29 degrees because multiple-thread worms are used to obtain higher efficiency, and larger thread angles are necessary in order to avoid excessive under-cutting of the worm-wheel teeth. According to the recommended practice of the American Gear Manufacturers' Association, worms having triple and quadruple threads should have a thread angle of 40 degrees, and some manufacturers of worm gearing, especially when the helix or lead angle of the thread is quite large, use a thread angle of 60 degrees.

If the helix or lead angle of the worm thread exceeds 15 or 20 degrees, it is common practice to reduce the depth of the thread by using the normal instead of the axial pitch of the worm in the formulas. Thus, if P_n equals normal pitch, the total depth equals $P_n \times 0.6866$ instead of $P_n = 0.6866$. This normal pitch P_n , equals $P_n \times \cos$ of the helix angle. According to the recommended practice of the American Gear Manufacturers' Association, the whole depth for single- and double-thread worms equals $P_n \times 0.686$, and for triple and quadruple-thread worms equals $P_n \times 0.623$.

Wormgear Hobs.—An ideal hob would have exactly the same pitch diameter and lead angle as the worm; repeated sharpening, however, would reduce the hob size because of the form-relieved teeth. Hence, the general practice is to make hobs (especially the radial or in-feed type) "over-size" to provide a grinding allowance and increase the hob life. An over-size hob has a larger pitch diameter and smaller lead angle than the worm, but repeated sharpenings gradually reduce these differences. To compensate for the smaller lead angle of an over-size hob, the hob axis may be set 90-degrees relative to the wormgear axis plus the difference between the lead angle of the worm at the pitch line, and the lead angle of the over-size hob at its pitch line. This angular adjustment is in the direction required to increase the inclination of the wormgear teeth so that the axis of the assembled worm will be 90 degrees from the wormgear axis. ("Lead angle" is measured from a plane perpendicular to worm or hob axis.)

Hob Diameter Formulas: If

D = pitch diameter of worm;

D_h = pitch diameter of hob;

A = addendum of worm and wormgear;

C = clearance between worm and worm-gear;

S = increase in hob diameter or "over-size" allowance for sharpening.

Outside diameter O of hob = $D + 2A + 2C + S$

Root diameter of hob = $D - 2A$

Pitch diameter D_h of hob = $O - (2A + 2C)$

Sharpening Allowance: Hobs for ordinary commercial work are given the following sharpening allowance, according to the recommended practice of the AGMA: In this for-

mula, h = helix angle of hob at outside diameter measured from axis; H = helix angle of hob at pitch diameter measured from axis.

$$\text{Sharpening allowance} = 0.075 \times \text{normal pitch} \times \left[\frac{16 - (h - H)}{16} \right] + 0.010$$

Number of Flutes or Gashes in Hobs: For finding the approximate number of flutes in a hob, the following rule may be used: Multiply the diameter of the hob by 3, and divide this product by twice the linear pitch. This rule gives suitable results for hobs for general purposes. Certain modifications, however, are necessary as explained in the following paragraph.

It is important that the number of flutes or gashes in hobs bear a certain relation to the number of threads in the hob and the number of teeth in the wormgear to be hobbled. In the first place, avoid having a common factor between the number of threads in the hob and the number of flutes; that is, if the worm is double-threaded, the number of gashes should be, say, 7 or 9, rather than 8. If it is triple threaded, the number of gashes should be 7 or 11, rather than 6 or 9. The second requirement is to avoid having a common factor between the number of threads in the hob and the number of teeth in the wormgear. For example, if the number of teeth in the wheel is 28, it would be best to have the hob triple-threaded, as 3 is not a factor of 28. Again, if there were to be 36 threads in the wormgear, it would be preferable to have 5 threads in the hob.

The cutter used in gashing hobs should be from $\frac{1}{8}$ to $\frac{1}{4}$ inch thick at the periphery, according to the pitch of the thread of the hob. The width of the gash at the periphery of the hob should be about 0.4 times the pitch of the flutes. The cutter should be sunk into the hob blank so that it reaches from $\frac{3}{16}$ to $\frac{1}{4}$ inch below the root of the thread.

Helical Fluted Hobs.—Hobs are generally fluted parallel with the axis, but it is obvious that the cutting action will be better if they are fluted on a helix at right angles with the thread helix. The difficulty of relieving the teeth with the ordinary backing-off attachment is the cause for using a flute parallel with the axis. Flutes cut at right angles to the direction of the thread can, however, also be relieved, if the angle of the flutes is slightly modified. In order to relieve hobs with a regular relieving attachment, it is necessary that the number of teeth in one revolution along the thread helix be such that the relieving attachment can be geared to suit it. The following method makes it possible to select an angle of flute that will make the flute come approximately at right angles to the thread, and at the same time the angle is so selected that the relieving attachment can be properly geared for relieving the hob.

Let

C = pitch circumference

T = developed length of thread in one turn;

N = number of teeth in one turn along thread helix;

F = number of flutes;

α = angle of thread helix.

Then $C \div F =$ length of each small division on pitch circumference;
 $(C \div F) \times \cos \alpha =$ length of division on developed thread;
 $C \div \cos \alpha = T$
 Hence

$$\frac{T}{(C \div F) \cos \alpha} = N = \frac{F}{\cos \alpha^2}$$

Now, if

$$\alpha = 30 \text{ degrees}, N = 1\frac{1}{3}F;$$

$$\alpha = 45 \text{ degrees}, N = 2F;$$

$$\alpha = 60 \text{ degrees}, N = 4F.$$

In most cases, however, such simple relations are not obtained. Suppose for example that $F = 7$, and $\alpha = 35$ degrees. Then $N = 10.432$, and no gears could be selected that would relieve this hob. By a very slight change in the helix angle of the flute, however, we can change N to 10 or $10\frac{1}{2}$; in either case we can find suitable gears for the relieving attachment.

The rule for finding the modified helical lead of the flute is: Multiply the lead of the hob by F , and divide the product by the difference between the desired values of N and F .

Hence, the lead of flute required to make $N = 10$ is:

$$\text{Lead of hob} \times (7 \div 3).$$

To make $N = 10\frac{1}{2}$, we have:

$$\text{Lead of flute} = \text{lead of hob} \times (7 \div 3.5).$$

From this the angle of the flute can easily be found.

That the rule given is correct will be understood from the following consideration. Change the angle of the flute helix β so that AG contains the required number of parts N desired. Then EG contains $N - F$ parts. But $\cot \beta = BD \div ED$ and by the law of similar triangles,

$$BD = \frac{F}{N} \times BG, \text{ and } ED = \frac{N - F}{N} C$$

The lead of the helix of the flute, however, is $C \times \cot \beta$.

Hence, the required lead of the helix of the flute:

$$C \times \cot \beta = \frac{F}{N - F} L$$

This formula makes it possible always to flute hobs so that they can be conveniently relieved, and at the same time have the flutes at approximately right angles to the thread.

Gear Shaving

The purpose of gear shaving is to correct errors in indexing, helix angle, tooth profile, and eccentricity by removing small amounts of material from the working surfaces of gear teeth. Special shaving cutters are used and have tooth flanks with sharp-edged grooves that traverse the tooth surfaces of the gear to be corrected as the hardened, driven cutter and the softer (30-35 Rockwell C) free-running gear are rotated in mesh on crossed axes in a special machine. The crossed angle is usually between 10 and 15 degrees, or half the difference between the helix angles of cutter and gear. In conventional shaving, the gear is held between live centers on the machine table, which is moved parallel to the gear axis, and is fed into contact with the cutter at each successive stroke of the table. Cutter speeds of up to 450 surface feet/min are commonly used.

The crossed axes cause the sharp-edged grooves on the cutter to traverse the tooth surfaces on the gear as cutter and gear rotate, resulting in a shearing action that cuts fine slivers from the gear tooth surfaces. At the same time, contact between the meshing sets of teeth has a burnishing action on the gear teeth, improving the surface finish. Shaving can remove 60-80 per cent of errors in a gear, and can produce accuracies of 0.0002 in. on the involute profile, 0.0003 in. on tooth-to-tooth spacing, and 0.0002 in. on lead or parallelism.

Gear-shaving machines have built-in mechanisms that can be used to rock the table as it traverses, producing crowned gear teeth that are slightly thicker at the center than at the ends. In the faster diagonal shaving method, the traversing movement of the table is at an angle to the gear axis, so that the cutter grooves move more rapidly across the gear, increasing the shaving action.

MISCELLANEOUS TOPICS**Mathematics**

Catenary Curve.—The catenary is the curve assumed by a string or chain of uniform weight hanging freely between two supports. The cables of a suspension bridge, if uniformly loaded, assume the form of the catenary curve. It has, therefore, considerable importance in structural engineering.

Mechanics

Running Balance.—When a part such as a drum, rotor, crankshaft, pulley, etc., is properly tested for balance while revolving, and any appreciable lack of balance is corrected on the basis of such test, the part is said to be in running or dynamic balance. Special balancing machines are used to determine the magnitude and location of unbalanced masses while the part is revolving; hence, the test is applied under operating conditions, which is not true of the test for static or standing balance.

Properties of Materials

Copper-Clad Steel.—A material generally used in the form of wire, in which a steel wire is covered with a coating of copper. It is produced either by alloying the copper with the surface of the metal or by welding it onto the surface. When the copper is alloyed with the surface, it is brought to a molten state before being applied, while, when welded to the surface, it is merely in a plastic state.

Truflex.—Thermostatic bimetal made in different types for automatically controlling temperature ranges of from —50 degrees F. to 1000 degrees F. Used for automatically controlling the operation of devices either heated or cooled by electricity, oil, or gas, as, for example: electric refrigerators, irons, toasters, gas ranges, water heaters, and domestic oil burners. Available in helical and spiral coils, rings, flat pieces, U-shapes, and in sheets up to 8 inches wide.

Firebrick Properties.—Brick intended for use in furnaces, flues, and cupolas, where the brickwork is subjected to very high temperatures, is generally known as "firebrick." There are several classes of firebrick, such as fireclay brick, silica brick, bauxite brick, chrome brick, and magnesia brick.

Ordinary firebricks are made from fireclay; that is, clays which will stand a high temperature without fusion, excessive shrinkage, or warping. There is no fixed standard of refractoriness for fireclay, but, as a general rule, no clay is classed as a fireclay that fuses below 2900 degrees F.

Fireclays vary in composition, but they all contain high percentages of alumina and silica, and only small percentages of such constituents as oxide of iron, magnesia, lime, soda, and potash. A great number of different kinds of firebrick are manufactured to meet the various conditions to which firebricks are subjected. Different classes of bricks are required to withstand different temperatures, as well as the corrosive action of gases, the chemical action of furnace charges, etc.

The most common firebrick will melt at a temperature ranging from 2830 to 3140 degrees F.; bauxite brick, from 2950 to 3245 degrees F.; silica brick, from 3090 to 3100 degrees F.; chromite brick, at 3720 degrees F.; and magnesia brick, at 4950 degrees F.

Inconel.—This heat resistant alloy retains its strength at high heats, resists oxidation and corrosion, has a high creep strength and is non-magnetic. It is used for high temperature applications (up to 2000 degrees F.) such as engine exhaust manifolds and furnace and heat treating equipment. Springs operating at temperatures up to 700 degrees F. are also made from it.

Approximate Composition: Nickel, 76; copper, 0.20; iron, 7.5; chromium, 15.5; silicon, 0.25; manganese, 0.25; carbon, 0.08; and sulphur, 0.007.

Physical Properties: Wrought Inconel in the annealed, hot-rolled, cold-drawn, and hard temper cold-rolled conditions exhibits yield strengths (0.2 per cent offset) of 35,000, 60,000, 90,000, and 110,000 pounds per square inch, respectively; tensile strengths of 85,000, 100,000, 115,000, and 135,000 pounds per square inch, respectively; elongations in 2 inches of 45, 35, 20, and 5 per cent, respectively; and Brinell hardnesses of 150, 180, 200, and 260, respectively.

Inconel "X".—This alloy has a low creep rate, is age-hardenable and non-magnetic, resists oxidation and exhibits a high strength at elevated temperatures. Uses include the making of bolts and turbine rotors used at temperatures up to 1500 degrees F., aviation brake drum springs and relief valve and turbine springs with low load loss or relaxation for temperatures up to 1000 degrees F.

Approximate Composition: Nickel, 73; copper, 0.2 maximum; iron, 7; chromium, 15; aluminum, 0.7; silicon, 0.4; manganese, 0.5; carbon, 0.04; sulphur, 0.007; columbium, 1; and titanium, 2.5.

Average Physical Properties: Wrought Inconel "X" in the annealed and age-hardened hot-rolled conditions exhibits yield strengths (0.2 per cent offset) of 50,000 and 120,000 pounds per square inch, respectively; tensile strengths of 115,000 and 180,000 pounds per square inch, respectively; elongations in 2 inches of 50 and 25 per cent, respectively; and Brinell hardnesses of 200 and 360, respectively.

Lodestone.—The most highly magnetic substances are iron and steel. Nickel and cobalt are also magnetic, but in a less degree. The name "magnet" has been derived from that of Magnesia, a town in Asia Minor, where an iron ore was found in early days which had the power of attracting iron.

This ore is known as magnetite and consists of about 72 per cent, by weight, of iron and 28 per cent of oxygen, the chemical formula being Fe_3O_4 . The ore possessing this magnetic property is also known as lodestone. If a bar of hardened steel is rubbed with a piece of lodestone, it will acquire magnetic properties similar to those of the lodestone itself.

Metallography.—The science or study of the microstructure of metal is known by most metallurgists as "metallography." The name "crystallography" is also used to some extent. The examination of metals and metal alloys by the aid of the microscope has become one of the most effective methods of studying their properties, and it is also a valuable means of controlling the quality of manufactured metallic articles and of testing the finished product. In preparing the specimen to be examined, a flat surface is first formed by filing or grinding, and this surface is then given a high polish, which is later subjected to the action of a suitable acid or etching reagent, in order to reveal clearly the internal structure of the metal when the specimen is examined under the microscope. This process shows clearly to an experienced observer the effect of variation in composition, heat-treatment, etc., and in many cases it has proved a correct means of determining certain properties of industrial products that a chemical analysis has failed to reveal.

Preparing Hardened Steel for Microscopic Study: To cause the constituents of the specimen to contrast with one another as seen through the microscope is the desired end, and a reagent is used which acts differently towards these elements; generally this reagent acts on one element more than on another so that the one least affected reflects the light from the faces of its crystals while the etched part absorbs the light, and, therefore, appears dark when photographed.

In etching specimens to develop the constituents of hardened anti tempered steels, very good results are obtained with sulphurous acid that is composed of 4 parts of sulphur dioxide to 96 parts of distilled water. The specimens are immersed in this, face upward, and removed as soon as the polished surface is frosted. This takes from 7 seconds to 1 minute.

They are then rinsed with water and dried with alcohol. Very thin layers of iron sulphide are deposited on the different constituents in different thicknesses, and this gives them different colors. Austenite remains a pale brown; martensite is given a pale blue and deep blue and brown color; troostite is made very dark; sorbite is uncolored; cementite exhibits a brilliant white; and ferrite is made dark brown. When the etching has proceeded to the desired extent, the specimen is at once washed thoroughly in order to remove all trace of the etching reagent. Usually it is simply rinsed with water, but frequently the washing is done with absolute alcohol, while ether and chloroform are also sometimes used.

The apparatus used for examining the etched surfaces of metals is composed of a microscope and camera combined with an arc lamp or other means of illumination.

Microscopic Study of Steel: Steel, in particular, shows many changes of structure due to the mechanical and thermal treatment, so that the microscope has become a very valuable instrument with which to inspect steel. To one who understands what the different formations of crystalline structure denote, the magnified surface reveals the temperature at which the steel was hardened, or at which it was drawn, and the depth to which the hardness penetrated. It also shows whether the steel was annealed or casehardened, as well as the depth to which the carbon penetrated. The carbon content can be closely judged, when the steel is annealed, and also how much of it is in the graphitic state in the high carbon steels. The quantity of special elements that is added to steel, such as nickel, chromium, tungsten, etc., can also be estimated, when the alloy to be examined has been put through its prescribed heat-treatment. Likewise, the impurities that may be present are clearly seen, regardless of whether they are of solid or gaseous origin.

Micarta.—Micarta is a non-metallic laminated product of specially treated woven fabric. By means of the various processes through which it is passed, it becomes a homogenous structure with physical properties which make it especially adapted for use as gears and pinions. Micarta can be supplied either in plate form or cut into blanks. It may also be molded into rings or on metal hubs for applications such as timing gears, where quantity production is attained. Micarta may be machined in the ordinary manner with standard tools and equipment.

Micarta gears do not require shrouds or end plates except where it is desired to provide additional strength for keyway support or to protect the keyway and bore against rough usage in mounting drive fits and the like. When end plates for hub support are employed they should extend only to the root of the tooth or slightly less.

Properties: The physical and mechanical properties of Micarta are as follows: weight per cubic inch, 0.05 pound; specific gravity, 1.4; oil absorption, practically none; shrinkage, swelling or warping, practically none up to 100 degrees C.; coefficient of expansion per inch per degree Centigrade, 0.00002 inch in the direction parallel to the laminations (edgewise), 0.00009 inch in the direction perpendicular to the laminations (flat wise); tensile strength, edgewise, 10,000 pounds per square inch; compressive strength, flat wise, 40,000 pounds per square inch; compressive strength, edgewise, 20,000 pounds per square inch; bending strength, flatwise, 22,000 pounds per square inch; bending strength, edgewise, 20,000 pounds per square inch.

Monel.—This general purpose alloy is corrosion-resistant, strong, tough and has a silvery-white color. It is used for making abrasion- and heat-resistant valves and pump parts, propeller shafts, laundry machines, chemical processing equipment, etc.

Approximate Composition: Nickel, 67; copper, 30; iron, 1.4; silicon, 0.1; manganese, 1; carbon, 0.15; and sulphur 0.01.

Average Physical Properties: Wrought Monel in the annealed, hot-rolled, cold-drawn, and hard temper cold-rolled conditions exhibits yield strengths (0.2 per cent offset) of 35,000, 50,000, 80,000, and 100,000 pounds per square inch, respectively; tensile strengths of 75,000, 90,000, 100,000, and 110,000 pounds per square inch, respectively;

elongations in 2 inches of 40, 35, 25, and 5 per cent, respectively; and Brinell hardnesses of 125, 150, 190, and 240, respectively.

“R” Monel.—This free-cutting, corrosion resistant alloy is used for automatic screw machine products such as bolts, screws and precision parts.

Approximate Composition: Nickel, 67; copper, 30; iron, 1.4; silicon, 0.05; manganese, 1; carbon, 0.15; and sulphur, 0.035.

Average Physical Properties: In the hot-rolled and cold-drawn conditions this alloy exhibits yield strengths (0.2 per cent offset) of 45,000 and 75,000 pounds per square inch, respectively; tensile strengths of 85,000 and 90,000 pounds per square inch, respectively; elongations in 2 inches of 35, and 25 per cent, respectively; and Brinell hardnesses of 145 and 180, respectively.

“K” Monel.—This strong and hard alloy, comparable to heat-treated alloy steel, is age-hardenable, non-magnetic and has low-sparking properties. It is used for corrosive applications where the material is to be machined or formed, then age hardened. Pump and valve parts, scrapers, and instrument parts are made from this alloy.

Approximate Composition: Nickel, 66; copper, 29; iron, 0.9; aluminum, 2.75; silicon, 0.5; manganese, 0.75; carbon, 0.15; and sulphur, 0.005.

Average Physical Properties: In the hot-rolled, hot-rolled and age-hardened, cold-drawn, and cold-drawn and age-hardened conditions the alloy exhibits yield strengths (0.2 per cent offset) of 45,000, 110,000, 85,000, and 115,000 pounds per square inch, respectively; tensile strengths of 100,000, 150,000, 115,000, and 155,000 pounds per square inch, respectively; elongations in 2 inches of 40, 25, 25, and 20 per cent, respectively; and Brinell hardnesses of 160, 280, 210, and 290, respectively.

“KR” Monel.—This strong, hard, age-hardenable and non-magnetic alloy is more readily machinable than “K” Monel. It is used for making valve stems, small parts for pumps, and screw machine products requiring an age-hardening material that is corrosion-resistant.

Approximate Composition: Nickel, 66; copper, 29; iron, 0.9; aluminum, 2.75; silicon, 0.5; manganese, 0.75; carbon, 0.28; and sulphur, 0.005.

Average Physical Properties: Essentially the same as “K” Monel.

“S” Monel.—This extra hard casting alloy is non-galling, corrosion-resisting, non-magnetic, age-hardenable and has low-sparking properties. It is used for gall-resistant pump and valve parts which have to withstand high temperatures, corrosive chemicals and severe abrasion.

Approximate Composition: Nickel, 63; copper, 30; iron, 2; silicon, 4; manganese, 0.75; carbon, 0.1; and sulphur, 0.015.

Average Physical Properties: In the annealed sand-cast, as-cast sand-cast, and age-hardened sand-cast conditions it exhibits yield strengths (0.2 per cent offset) of 70,000, 100,000, and 100,000 pounds per square inch, respectively; tensile strengths of 90,000, 130,000, and 130,000 pounds per square inch, respectively; elongations in 2 inches of and 3, 2, and 2 per cent, respectively; and Brinell hardnesses of 275, 320, and 350, respectively.

“H” Monel.—An extra hard casting alloy with good ductility, intermediate strength and hardness that is used for pumps, impellers and steam nozzles.

Approximate Composition: Nickel, 63; copper, 31; iron, 2; silicon, 3; manganese, 0.75; carbon, 0.1; and sulphur, 0.015.

Average Physical Properties: In the as-cast sand-cast condition this alloy exhibits a yield strength (0.2 per cent offset) of 60,000 pounds per square inch, a tensile strength of 100,000 pounds per square inch, an elongation in 2 inches of 15 per cent and a Brinell hardness of 210.

Nichrome.—“Nichrome” is the trade name of an alloy composed of nickel and chromium, which is practically non-corrosive and far superior to nickel in its ability to withstand high

temperatures. Its melting point is about 1550 degrees C. (about 2800 degrees F.). Nichrome shows a remarkable resistance to sulphuric and lactic acids. In general, nichrome is adapted for annealing and carburizing boxes, heating retorts of various kinds, conveyor chains subjected to high temperatures, valves and valve seats of internal combustion engines, molds, plungers and conveyors for use in the working of glass, wire baskets or receptacles of other form that must resist the action of acids, etc. Nichrome may be used as a substitute for other materials, especially where there is difficulty from oxidation, pitting of surfaces, corrosion, change of form, or lack of strength at high temperatures. It can be used in electrically-heated appliances and resistance elements. Large plates of this alloy are used by some manufacturers for containers and furnace parts, and when perforated, as screens for use in chemical sifting and ore roasting apparatus, for services where temperatures between 1700 degrees F. and 2200 degrees F. are encountered.

Strength of Nichrome: The strength of a nichrome casting, when cold, varies from 45,000 to 50,000 pounds per square inch. The ultimate strength at 200 degrees F. is 94,000 pounds per square inch; at 400 degrees F., 91,000 pounds per square inch; at 600 degrees F., 59,000 pounds per square inch; and at 800 degrees F., 32,000 pounds per square inch. At a temperature of 1800 degrees F., nichrome has a tensile strength of about 30,000 pounds per square inch, and it is tough and will bend considerably before breaking, even when heated red or white hot.

Nichrome in Cast Iron: Because of the irregularity of the castings, the numerous cores required, and the necessity for sound castings, gray iron with a high silicon content has been the best cast iron available to the automotive industry. Attempts have been made to alloy this metal in such a way that the strength and hardness would be increased, but considerable difficulty has been experienced in obtaining uniform results. Nickel has been added to the cupola with success, but in the case of automotive castings, where a large quantity of silicon is present, the nickel has combined with the silicon in forming large flakes of graphite, which, of course, softens the product. To offset this, chromium has also been added, but it has been uncertain just what the chromium content of the poured mixture should be, as a considerable amount of the chromium oxidizes.

Nichrome (Grade B) may be added to the ladle to obtain chromium and nickel in definite controllable amounts. The analysis of this nichrome is, approximately: Nickel, 60 per cent; chromium, 12 per cent; and iron, 24 per cent. It is claimed that the process produces castings of closer grain, greater hardness, greater resistance to abrasion, increased durability, improved machinability, and decreased brittleness. Nichrome-processed iron is suitable for casting internal-combustion engine cylinders; electrical equipment, where a control of the magnetic properties is desired; cast-iron cams; iron castings of thin sections where machinability and durability are factors; electrical resistance grids; pistons; piston-rings; and water, steam, gas, and other valves.

Nickel Alloy for Resisting Acids.—The resistance of nickel to acids is considerably increased by an addition of tantalum. Ordinarily from 5 to 10 per cent may be added, but the resistance increases with an increasing percentage of tantalum. An alloy of nickel with 30 per cent tantalum, for example, can be boiled in aqua regia or any other acid without being affected. The alloy is claimed to be tough, easily rolled, capable of being hammered or drawn into wire. The nickel loses its magnetic quality when alloyed with tantalum. The alloy can be heated in the open air at a high temperature without oxidizing. The method of producing the alloy consists in mixing the two metals in a powdered form, compressing them at high pressure, and bringing them to a high heat in a crucible or quartz tube in a vacuum. For general purposes, the alloy is too expensive.

Duronze.—An alloy of high resistance to wear and corrosion, composed of aluminum, copper, and silicon, with a tensile strength of 90,000 pounds per square inch. Developed for the manufacture of valve bushings for valves that must operate satisfactorily at high pressures and high temperatures without lubrication.

Aluminum Alloys, Wrought, Sheet.—*Physical Properties:* In the form of sheets, the tensile strength varies from 35,000 for soft temper to 62,000 pounds per square inch for heat-treated sheets, and the elongation in 2 inches from 12 to 18 per cent. The yield strength of a heat-treated sheet is about 40,000 pounds per square inch minimum.

Plow-steel Wire Rope.—The name “plow” steel originated in England and was applied to a strong grade of steel wire used in the construction of very strong ropes employed in the mechanical operation of plows. The name “plow” steel, however, has become a commercial trade name, and, applied to wire, simply means a high-grade open-hearth steel of a tensile strength in wire of from 200,000 to 260,000 pounds per square inch of sectional area. A strength of 200,000 pounds per square inch is obtained in wire about 0.200 inch in diameter. Plow steel when used for wire ropes has the advantage of combining lightness and great strength. It is a tough material, but not as pliable as crucible steel. The very highest grade of steel wire used for wire rope is made from special steels ranging in tensile strength in wire from 220,000 to 280,000 pounds per square inch of sectional area. This steel is especially useful when great strength, lightness, and abrasive resisting qualities are required.

Type Metal.—Antimony gives to metals the property of expansion on solidification, and hence, is used in type metal for casting type for the printing trades to insure completely filling the molds. Type metals are generally made with from 5 to 25 per cent of antimony, and with lead, tin and sometimes a small percentage of copper as the other alloying metals.

The compositions of a number of type metal alloys are as follows (figures given are percentages): lead 77.5, tin 6.5, antimony 16; lead 70, tin, 10, antimony 18, copper, 2; lead 63.2, tin 12, antimony 24, copper 0.8; lead 60.5, tin 14.5, antimony 24-25, copper 0.75; lead 60, tin 35, antimony 5; and lead 55.5, tin 40, antimony 4.5.

A high grade of type metal is composed of the following percentages: lead 50; tin 25; and antimony 25.

Vanadium Steel.—The two most marked characteristics of vanadium steel are its high tensile strength and its high elastic limit. Another equally important characteristic is its great resistance to shocks; vanadium steel is essentially a non-fatigue metal, and, therefore, does not become crystallized and break under repeated shocks like other steels. Tests of the various spring steels show that, when subjected to successive shocks for a considerable length of time, a crucible carbon-steel spring was broken by 125,000 alternations of the testing machine, while a chrome-vanadium steel spring withstood 5,000,000 alternations, remaining unbroken. Another characteristic of vanadium steel is its great ductility. Highly-tempered vanadium-steel springs may be bent sharply, in the cold state, to an angle of 90 degrees or more, and even straightened again, cold, without a sign of fracture; vanadium-steel shafts and axles may be twisted around several complete turns, in the cold state, without fracture. This property, combined with its great tensile strength, makes vanadium steel highly desirable for this class of work, as well as for gears which are subjected to heavy strains or shocks upon the teeth. Chromium gives to steel a brittle hardness which makes it very difficult to forge, machine, or work, but vanadium, when added to chrome-steel, reduces this brittle hardness to such an extent that it can be machined as readily as an 0.40-per-cent carbon steel, and it forges much more easily. Vanadium steels ordinarily contain from 0.16 to 0.25 per cent of vanadium. Steels of this composition are especially adapted for springs, car axles, gears subjected to severe service, and for all parts which must withstand constant vibration and varying stresses. Vanadium steels containing chromium are used for many automobile parts, particularly springs, axles, driving-shafts, and gears.

Wood's Metal.—The composition of Wood's metal, which is a so-called “fusible metal,” is as follows: 50 parts of bismuth, 25 parts of lead, 12.5 parts of tin and 12.5 parts of cadmium. The melting point of this alloy is from 66 to 71 degrees centigrade (151 to 160 degrees F. approximately).

Lumber.—Lumber is the product of the saw and planing mill not further manufactured than by sawing, resawing, and passing lengthwise through a standard planing machine, cross-cutting to length and working. When not in excess of one-quarter inch thickness and intended for use as veneering it is classified as veneer. According to the Simplified Practice Recommendations promulgated by the National Bureau of Standards, lumber is classified by its principal use as: yard lumber, factory and shop lumber, and structural lumber.

Yard lumber is defined as lumber of all sizes and patterns which is intended for general building purposes. Its grading is based on intended use and is applied to each piece without reference to size and length when graded and without consideration to further manufacture. As classified by size it includes: strips, which are yard lumber less than 2 inches thick and less than 8 inches wide; boards, which are yard lumber less than 2 inches thick but 8 inches or more wide; dimension, which includes all yard lumber except strips, boards and timbers; and timbers, which are yard lumber of 5 or more inches in the least dimension.

Factory and shop lumber is defined as lumber intended to be cut up for use in further manufacture. It is graded on the basis of the percentage of the area which will produce a limited number of cuttings of a specified, or of a given minimum, size and quality.

Structural lumber is defined as lumber that is 2 or more inches thick and 4 or more inches wide, intended for use where working stresses are required. The grading of structural lumber is based on the strength of the piece and the use of the entire piece. As classified by size and use it includes *joists* and *planks*—lumber from 2 inches to but not including 5 inches thick, and 4 or more inches wide, of rectangular cross section and graded with respect to its strength in bending, when loaded either on the narrow face as joist or on the wide face as plank; *beams* and *stringers*—lumber of rectangular cross section 5 or more inches thick and 8 or more inches wide and graded with respect to its strength in bending when loaded on the narrow face; and *posts* and *timbers*—pieces of square or approximately square cross section 5 by 5 inches and larger and graded primarily for use as posts or columns carrying longitudinal load, but adapted to miscellaneous uses in which strength in bending is not especially important.

Lumber, Manufactured.—According to the Simplified Practice Recommendations promulgated by the National Bureau of Standards, lumber may be classified according to the extent which it is manufactured as:

Rough lumber which is lumber that is undressed as it comes from the saw.

Surfaced lumber which is lumber that is dressed by running it through a planer and may be surfaced on one or more sizes and edges.

Worked lumber which is lumber that has been run through a matching machine, sticker or molder and includes: *matched lumber* which has been worked to provide a close tongue-and-groove joint at the edges or, in the case of end-matched lumber, at the ends also; *ship-lapped lumber* which has been worked to provide a close rabbetted or lapped joint at the edges; and *patterned lumber* which has been shaped to a patterned or molded form.

Lumber Water Content.—The origin of lumber has a noticeable effect on its water content. Lumber or veneer (thin lumber produced usually by rotary cutting or flat slicing, sometimes by sawing), when produced from the log, contains a large proportion of water, ranging from 25 to 75 per cent of the total weight. One square foot (board measure, one inch thick) of gum lumber, weighing approximately five pounds when sawed, will be reduced to about three pounds when its water content of approximately one quart has been evaporated. Oak grown on a hillside may contain only a pint (approximately 1 lb.) and swamp gum may have from 2 to 4 pints of water per square foot, board measure. This water content of wood exists in two forms—free moisture and cell moisture. The former is readily evaporable in ordinary air drying, but the latter requires extensive air drying (several years) or artificial treatment in kilns. It is possible to use artificial means to remove the free moisture, but a simple air exposure is usually more economical.

Dimensioning, Gaging, and Measuring

Transfer Calipers.—Calipers provided with an auxiliary arm which can be located so that the calipers may be opened or closed to the original setting, if required. Calipers of this type are generally used for inside measurements, and are employed for measuring recesses where it is necessary to move the caliper points in order to remove the calipers from the place where the measurement is taken.

Wheatstone Bridge.—The most generally used method for the measurement of the ohmic resistance of conductors is by the use of the *Wheatstone bridge*. In a simple form (See Fig. 1.) it comprises two resistance coils the ratio of the resistances of which is known, and a third, generally adjustable, resistance of known value. These are connected in circuit with the unknown resistance to be measured, a galvanometer, and a source of current, as in the diagram.

Fig. 1. Wheatstone Bridge

The adjustable resistance and the "bridge arms," if necessary, are adjusted until the galvanometer indicates no flow of current. The value of the unknown resistance is thus measured in terms of the known resistance and the known ratio of the bridge arms. In the diagram, R_1 , R_2 , R_3 , and R_4 are resistances; B a source of electromotive force and I_1 , I_2 , I_3 and I_4 currents through the resistances; G is a galvanometer. If the relation of the various resistances is such that no current flows through G , then I_1 equals I_2 , and I_3 equals I_4 ; also I_1R_1 equals I_3R_3 , and I_2R_2 equals I_4R_4 , there being no electromotive forces in the triangles R_1R_3G and R_2R_4G . It follows, therefore, that

$$\frac{I_1}{I_3} = \frac{R_3}{R_1}, \quad \text{and} \quad \frac{I_2}{I_4} = \frac{R_4}{R_2}$$

and hence, as

$$\frac{I_1}{I_3} = \frac{I_2}{I_4}, \quad \text{it follows that} \quad \frac{R_3}{R_1} = \frac{R_4}{R_2}$$

If one of these resistances, R_1 for instance, is unknown, it may then be found through the equation:

$$R_1 = \frac{R_2 R_3}{R_4}$$

Wheatstone bridges are made in many forms. The three known resistances are made adjustable and are usually made of many spools of special resistance wire. The resistances are usually varied by short-circuiting a greater or smaller number of these spools.

Tools and Tooling

Rotary Files and Burs.—Rotary files and burs are used with power-operated tools, such as flexible- or stationary-shaft machines, drilling machines, lathes, and portable electric or pneumatic tools, for abrading or smoothing metals and other materials. Corners can be broken and chamfered, burs and fins removed, holes and slots enlarged or elongated, and scale removed in die-sinking, metal patternmaking, mold finishing, toolmaking and casting operations.

The difference between rotary files and rotary burs, as defined by most companies, is that the former have teeth cut by hand with hammer and chisel, whereas the latter have teeth or flutes ground from the solid blank after hardening, or milled from the solid blank before hardening. (At least one company, however prefers to differentiate the two by use and size: The larger-sized general purpose tools with $\frac{1}{4}$ -inch shanks, whether hand cut or ground, are referred to as rotary files; the smaller shanked $\frac{1}{8}$ -inch – and correspondingly smaller-headed tools used by diesinkers and jewelers are referred to as burs.) Rotary files are made from high-speed steel and rotary burs from high-speed steel or cemented carbide in various cuts such as double extra coarse, extra coarse or rough, coarse or standard, medium, fine, and smooth. Standard shanks are $\frac{1}{4}$ inch in diameter.

There is very little difference in the efficiency of rotary files or burs when used in electric tools and when used in air tools, provided the speeds have been reasonably well selected. Flexible-shaft and other machines used as a source of power for these tools have a limited number of speeds which govern the revolutions per minute at which the tools can be operated.

The carbide bur may be used on hard or soft materials with equally good results. The principal difference in construction of the carbide bur is that its teeth or flutes are provided with negative rather than a radial rake. Carbide burs are relatively brittle and must be treated more carefully than ordinary burs. They should be kept cutting freely, in order to prevent too much pressure, which might result in crumbling of the cutting edges.

At the same speeds, both high-speed steel and carbide burs remove approximately the same amount of metal. However, when carbide burs are used at their most efficient speeds, the rate of stock removal may be as much as four times that of ordinary burs. It has been demonstrated that a carbide bur will last up to 100 times as long as a high-speed steel bur of corresponding size and shape.

Tooth-rest for Cutter Grinding.—A tooth-rest is used to support a cutter while grinding the teeth. For grinding a cylindrical cutter having helical or "spiral" teeth, the tooth-rest must remain in a fixed position relative to the grinding wheel. The tooth being ground will then slide over the tooth-rest, thus causing the cutter to turn as it moves longitudinally, so that the edge of the helical tooth is ground to a uniform distance from the center, throughout its length. For grinding a straight-fluted cutter, it is also preferable to have the tooth-rest in a fixed position relative to the wheel, unless the cutter is quite narrow, because any warping of the cutter in hardening will result in inaccurate grinding, if the toothrest moves with the work. The tooth-rest should be placed as close to the cutting edge of the cutter as is practicable, and bear against the face of the tooth being ground.

Machining Operations

Feed Rate on Machine Tools.— The rate of feed as applied to machine tools in general, usually indicates (1) the movement of a tool per work revolution, (2) the movement of a tool per tool revolution, (3) or the movement of the work per tool revolution.

Rate of Feed in Turning: The term "feed" as applied to a lathe indicates the distance that the tool moves during each revolution of the work. There are two ways of expressing the rate of feed. One is to give the actual tool movement per work revolution in thousandths of an inch. For example, the range of feeds may be given as 0.002 to 0.125 inch. This is the usual method. Another way of indicating a feed range is to give the number of cuts per inch or the number of ridges that would be left by a pointed tool after turning a length of one inch. For example, the feed range might be given as 8 to 400. In connection with turning and other lathe operations, the feed is regulated to suit the kind of material, depth of cut, and in some cases the finish desired.

Rate of Feed in Milling: The feed rate of milling indicates the movement of the work per cutter revolution.

Rate of Feed in Drilling: The rate of feed on drilling machines ordinarily indicates the feeding movement of the drill per drill revolution.

Rate of Feed in Planing: On planers, the rate of feed represents the tool movement per cutting stroke. On shapers, which are also machines of the planing type, the rate of feed represents the work movement per cutting stroke.

Rate of Feed on Gear Hobbing: The feed rate of a gear hobbing machine represents the feeding movement of the hob per revolution of the gear being hobbled.

Feed on Grinding Machines: The traversing movement in grinding is equivalent to the feeding movement on other types of machine tools and represents either the axial movement of the work per work revolution or the traversing movement of the wheel per work revolution, depending upon the design of the machine.

Billet.— A "billet," as the term is applied in rolling mill practice, is square or round in section and from 1½ inches in diameter or square to almost 6 inches in diameter or square. Rolling mills used to prepare the ingot for the forming mills are termed "blooming mills," "billet mills," etc.

Milling Machines, Lincoln Type.—The well-known Lincoln type of milling machine is named after George S. Lincoln of the firm then known as George S. Lincoln & Co., Hartford, Conn. Mr. Lincoln, however, did not originate this type but he introduced an improved design. Milling machines constructed along the same general lines had previously been built by the Phoenix Iron Works of Hartford, Conn., and also by Robbins & Lawrence Co., of Windsor, Vt. Milling machines of this class are intended especially for manufacturing and are not adapted to a great variety of milling operations, but are designed for machining large numbers of duplicate parts. Some milling machines which are designed along the same lines as the Lincoln type are referred to as the *manufacturing type*. The distinguishing features of the Lincoln type are as follows: The work table, instead of being carried by an adjustable knee, is mounted on the solid bed of the machine and the outer arbor support is also attached directly to the bed. This construction gives a very rigid support both for the work and the cutter. The work is usually held in a fixture or vise attached to the table, and the milling is done as the table feeds longitudinally. The table is not adjustable vertically but the spindle head and spindles can be raised or lowered as may be required.

Saddle.—A machine tool saddle is a slide which is mounted upon the ways of a bed, cross-rail, arm, or other guiding surfaces, and the saddle metal-cutting tools or a work-holding table. On holding either metal-cutting tools or a work-holding table. On a knee-type milling machine the saddle is that part which slides upon the knee and which supports the work-holding table. The saddle of a planer or boring mill is mounted upon the cross-rail

and supports the tool-holding slide. The saddle of a lathe is that part of a carriage which slide. The saddle of a lathe is that part of a carriage which slides directly upon the lathe bed and supports the cross-slide.

Cold Extrusion.—In simplest terms, cold extrusion can be defined as the forcing of unheated metal to flow through a shape-forming die. It is a method of shaping metal by plastically deforming it under compression at room temperature while the metal is within a die cavity formed by the tools. The metal issues from the die in at least one direction with the desired cross-sectional contour, as permitted by the orifice created by the tools.

Cold extrusion is always performed at a temperature well below the recrystallization temperature of the metal (about 1100 to 1300 degrees F. for steel) so that work-hardening always occurs. In hot extrusion, recrystallization eliminates the effects of work-hardening, unless rapid cooling of the extrusion prevents recrystallization from being completed.

Extrusion differs from other processes, such as drawing, in that the metal is always being pushed under compression and never pulled in tension. As a result, the material suffers much less from cracking. While coining is closely related to extrusion, it differs in that metal is completely confined in the die cavity instead of being forced through openings in the die. Some forging operations combine both coining and extrusion.

The pressure of the punch against the metal in an open die, and the resultant shaped part obtained by displacing the metal along paths of least resistance through an orifice formed between the punch and die, permits considerably higher deformation rates without tearing and large changes in the shape. Extrusion is characterized by a thorough kneading of the material. The cross-sectional shape of the part will not change due to expansion or contraction as it leaves the tool orifice. The term "cold extrusion" is not too descriptive and is not universally accepted. Other names for the same process include impact extrusion, extrusion-forging, cold forging, extrusion pressing, and heavy cold forming. Impact extrusion, however, is more frequently used to describe the production of non-ferrous parts, such as collapsible tubes and other components, while cold extrusion seems to be preferred by manufacturers of steel parts. In Germany, the practice is called *Kaltspritzen*—a literal translation of which is "cold-squirting."

One probable reason for not using impact extrusion in referring to the cold extrusion of steel is that the term implies plastic deformation by striking the metal an impact blow. Actually, the metal must be pushed through the die orifice, with pressure required over a definite period of time. One disadvantage of the terminology "cold extrusion" is the possible confusion with the older, more conventional direct extrusion process in which billets of hot metal are placed in a cylinder and pushed by a ram through a die (usually in a large, horizontal hydraulic press) to form rods, bars, tubes, or irregular shapes of considerable length.

Another possible disadvantage is the connotation of the word "cold." While the process is started with blanks, slugs, tubular sections, or pre-formed cups at room temperature, the internal, frictional resistance of the metal to plastic flow raises the surface temperature of the part to 400 degrees F. or more, and the internal temperature even higher (depending on the severity of the operation). These are still below the recrystallization temperature and the extrusions retain the advantages of improved physical properties resulting from the cold working.

Transfer Machines.—These specialized machine tools are used to perform various machining operations on parts or parts in fixtures as the parts are moved along on an automatic conveyor which is part of the machine tool set-up. In a set-up, the parts can move in a straight line from their entry point to their exit point, or the setup may be constructed in a U-shape so that the parts are expelled near where they start.

Fasteners

Stove Bolt.— This bolt has been so named because of its use in stove building. It is made in a number of different forms, either with a round button, or flat countersunk head, the head having a slot for a screwdriver and the threaded end being provided with a square or hexagon nut.

Flattening Test.— This term as applied to tubing refers to a method of testing a section of tubing by flattening it until the inside walls are parallel and separated by a given distance—usually equal to three times the wall thickness for seamless tubes and five times the wall thickness for lap-welded tubes. Boiler tubes subjected to this test should show no cracks or flaws. The flattening test applied to rivets, consists in flattening a rivet head while hot to a diameter equal to $2\frac{1}{2}$ times the diameter of the shank or body of the rivet. Good rivet steel must not crack at the edges of the flattened head.

Rivets, Cold Formed.— In permanently assembling various Light parts, it is often possible to greatly reduce the cost and yet secure sufficient strength by cold forming in an assembling die, the rivet or rivets as an integral part of one of the assembled sections. Figures 1a, 1b, and 1c illustrate how a steel spring is cold riveted to the heavier section. Plain round punches descend and form the rivets by forcing metal down through the holes in the spring (see Fig. 1b); the metal at the edge is then turned back by the die as shown in Fig. 1c, thus completing the riveting at one stroke of the press. In this particular case, about sixty assemblies per minute are obtained.

Embossed Dowels and Hubs: When dowel-pins are required to insure the accurate location of parts relative to each other, small projections or bosses may be formed directly on many die-made products, the projection being an integral part of the work and serving as a dowel-pin. Figure 1d illustrates how the dowel is formed. The method may be described as a partial punching operation, as a punch penetrate about one-half the stock thickness and forces the boss into a pocket in the die which controls the diameter and compresses the metal, thus forming a stronger projection than would be obtained otherwise. The height h of the dowel or boss should not exceed one-half of the dowel diameter d and h . should not exceed one-half of the stock thickness t . This is a practical rule which may be applied either to steel or non-ferrous metals, such as brass.

Fig. 1b.

Fig. 1c.

Fig. 1d.

Expansion Bolt.—When a through bolt cannot be used for attaching a pipe hanger, bracket, or other part, to a wall or ceiling of brick or concrete, what are known as *expansion bolts* are often used. The body of an expansion bolt is divided and the arrangement is such that, when the head of the bolt is turned, the sections forming the body of the bolt are forced outward and against the wall of the hole which has been drilled into the brick, concrete, or stone, as the case may be. Bolts of this type are made in quite a variety of designs. The nominal size represents the diameter of the bolt proper and not the diameter of the casing or expansion member.

Fig. 2. Expansion Bolt

Washers.—Plain washers are made in standard sizes to suit standard screw threads, bolts and screws. The manufacturers' regular standard, adopted in 1935, is for bolt sizes ranging from $\frac{1}{4}$ inch up to 3 inches, inclusive. There is also an S.A.E. standard for plain washers. This includes screw and bolt sizes ranging from No. 2 machine screw up to, and including, $1\frac{1}{2}$ -inch bolts. These washers are somewhat smaller than the manufacturers' standard and also have smaller inside diameters or clearance spaces between the bolt and washer.

Threads and Threading

History of Briggs Pipe Thread (NPT).—The USA (American) Standard for Pipe Threads, originally known as the Briggs Standard, was formulated by Mr. Robert Briggs. For several years around 1862 Mr. Briggs was superintendent of the Pascal Iron Works of Morris, Tasker & Company, Philadelphia, Pa., and later engineering editor of the "Journal" of the Franklin Institute. After his death on July 24, 1882, a paper by Mr. Briggs containing detailed information regarding American pipe and pipe thread practice, as developed by him when superintendent of the Pascal Iron Works, was read before the Institution of Civil Engineers of Great Britain. This is recorded in the Excerpt Minutes, Volume LXXI, Session 1882–1883, Part 1, of that Society.

It is of interest to note that the nominal sizes (diameters) of pipe ten (10) inches and under, and the pitches of the thread were for the most part established between 1820 and 1840.

By publishing his data, based on years of practice, Mr. Briggs was the means of establishing definite detail dimensions. The Briggs formula did not provide for the internal threads or gaging requirements for making taper threaded joints. It established only the external thread on pipe, with no tolerance.

In 1886 the large majority of American manufacturers threaded pipe to practically the Briggs Standard, and acting jointly with The American Society of Mechanical Engineers they adopted it as a standard practice that year, and master plug and ring gages were made.

Later at various conferences representatives of the manufacturers and the ASME established additional sizes, certain details of gaging, tolerances, special applications of the standard, and in addition tabulated the formulas and dimensions more completely than was done by Mr. Briggs.

Until the manufacturers adopted the Briggs thread in 1886, it seems that each manufacturer of necessity threaded his pipe and fittings according to his best judgment. After 1886 there was some attempt to work toward better interchangeability. However, the need for a better gaging practice resulted in the adoption of the thin ring gage and the truncation of the plug and ring gages to gage the flanks of the thread. This practice of threading fittings and couplings which provides threads to make up joints with a wrench was standardized about 1913.

In 1913 a Committee on the Standardization of Pipe Threads was organized for the purpose of re-editing and expanding the Briggs Standard. The American Gas Association and The American Society of Mechanical Engineers served as joint sponsors. After six years of work, this committee completed the revised standard for taper pipe thread which was published in the ASME "*Transactions*" of 1919, and was approved as an American Standard by the American Engineering Standards Committee, later named the American Standards Association in December 1919. It was the first standard to receive this designation under the ASA procedure, and was later published in pamphlet form.

In the years which followed, the need for a further revision of this American Standard became evident as well as the necessity of adding to it the recent developments in pipe threading practice. Accordingly, the Sectional Committee on the Standardization of Pipe Threads, B2, was organized in 1927 under the joint sponsorship of the A.G.A. and the ASME.

During the following 15 years, several meetings were held leading to approval by the members of the Sectional Committee, of the April 1941 draft. The revision was approved by the sponsors and ASA and published as an American Standard in October, 1942.

Shortly after publication of the 1942 standard, the Committee undertook preparation of a complete revision. The text and tables were rearranged and expanded to include Dryseal pipe threads, and an extensive appendix was added to provide additional data on the application of pipe threads and to record in abbreviated form the several special methods which were established for gaging some of the various applications of pipe threads.

The resulting proposal was approved by letter ballot of the Sectional Committee. Following its acceptance by the sponsor bodies, the draft was submitted to the American Standards Association and designated an American Standard on December 11, 1945.

At a subsequent meeting of the Sectional Committee it was agreed that for the convenience of users, the standards covering Dryseal pipe threads should be published under separate cover. Consequently, the section included in ASA B2.1-1945 on Dryseal pipe threads was deleted from the 1960 revision to that standard and used as a basis for the development of a separate proposal for Dryseal pipe threads. The text and tables were expanded to completely document the various series threads and gages, and appendices covering formulas, drilled hole sizes and special series threads were added. The E_j internal diameter and the L_j hand type engagements for the $\frac{1}{8}$ and $\frac{1}{4}$ inch sizes were revised to correct for a disproportionate number of threads for hand tight engagement. This proposal was approved by letter ballot vote of the Sectional Committee and submitted to the A.G.A. and the ASME. Following approval by the sponsor organizations, it was approved by the American Standards Association on April 29, 1960, and designated as ASA B2.1-1960, Pipe Threads (Except Dryseal).

The present revision of this standard constitutes a general updating. In line with their current policy, the A.G.A. has withdrawn sponsorship of this standard, while remaining active in the work of the standards committee. In compliance with the rules of the United States of America Standards Institute (formerly ASA) the previously designated Sectional Committees are now called Standards Committees.

Following approval by the Standards Committee B2 and the sponsor, ASME, the revision was approved by the United States of America Standards Institute on November 29, 1968.

Lock-Nut Pipe Thread.—The lock-nut pipe thread is a straight thread of the largest diameter which can be cut on a pipe. Its form is identical with that of the American or Briggs standard taper pipe thread. In general, “Go” gages only are required. These consist of a straight-threaded plug representing the minimum female lock-nut thread, and a straight-threaded ring representing the maximum male lock-nut thread. This thread is used only to hold parts together, or to retain a collar on the pipe. It is never used where a tight threaded joint is required.

Thread Grinding.—Thread grinding is applied both in the manufacture of duplicate parts and also in connection with precision thread work in the tool-room.

Single-edged Grinding Wheel: In grinding a thread, the general practice in the United States is to use a large grinding wheel (for external threads) having a diameter of possibly 18 to 20 inches. The width may be $5/16$ or $3/8$ inch. The face or edge of this comparatively narrow wheel is accurately formed to the cross-sectional shape of the thread to be ground. The thread is ground to the correct shape and lead by traversing it relative to the grinding wheel. This traversing movement, which is equivalent to the lead of the screw thread for each of its revolutions, is obtained from a lead-screw. On one type of thread grinder, this lead-screw is attached directly to the work-spindle and has the same lead as the screw thread to be ground; hence, there is a separate lead-screw for each different lead of thread to be ground. On another design of machine, the lead-screw arrangement is similar to that on a lathe in that the required lead on the ground thread is obtained by selection of the proper change gears. The grinding wheel may have a surface speed of 7000 feet a minute, whereas the work speed may range from 3 to 10 feet per minute. The grinding wheel is inclined to suit the helix angle of the thread and either right- or left-hand threads may be ground. Provision is also made for grinding multiple threads and for relieving taps and hobs. The wheel shape is accurately maintained by means of diamond truing tools. On one type of machine, this truing is done automatically and the grinding wheel is also adjusted automatically to compensate for whatever slight reduction in wheel size may result from the truing operation.

An internal thread may also be ground with a single-edged wheel. The operation is the same in principle as external thread grinding. The single-edged wheel is used whenever the highest precision is required, grinding the work either from the solid or as a finishing operation.

Grinding “from the Solid”: On some classes of work, the entire thread is formed by grinding “from the solid,” especially if the time required is less than would be needed for a rough thread-cutting operation followed by finish-grinding after hardening. Grinding threads from the solid is applied to the finer pitches. In some plants, threads with pitches up to about $1/16$ inch are always ground by this method.

Multi-edged Grinding Wheel: An entire screw thread, if not too long, may be ground completely in one revolution by using a multi-edged type of grinding wheel. The face of this wheel is formed of a series of annular thread-shaped ridges so that it is practically a number of wheels combined in one. The principle is the same as that of milling screw threads by the multiple-cutter method. If the length of the thread to be ground is less than the width of the wheel, it is possible to complete the grinding in practically one work revolution as in thread milling. A grinding wheel having a width of, say, $2\frac{1}{2}$ inches, is provided

with annual ridges or threads across its entire width. The wheel is fed in to the thread depth, and, while the work makes one single revolution, the wheel moves axially a distance equal to the thread lead along the face of the work. Most threads which require grinding are not longer than the width of the wheel; hence, the thread is completed by one turn of the work.

If the thread is longer than the wheel width, one method is to grind part of the thread and then shift the wheel axially one or more times for grinding the remaining part. For example, with a wheel $2\frac{1}{2}$ inches in width, a thread approximately 12 inches long might be ground in five successive steps. A second method is that of using a multi-edged tapering wheel which is fed axially along the work. The taper is to distribute the work of grinding over the different edges or ridges as the wheel feeds along.

Hand Chaser.—A hand chaser is a type of threading tool used either for cutting or chasing external or internal threads. The tool is supported upon a rest and is guided by the hand; it is used mainly on brass work, for slightly reducing the size of a thread that has been cut either by a die or threading tool. A hand chaser may also be used for truing up battered threads in repair work and for similar purposes.

Thread-Cutting Methods.—The two general methods of forming screw threads may be defined as the cutting method and the rolling or displacement method. The cutting methods as applied to external threads are briefly as follows:

1) By taking a number of successive cuts with a single-point tool that is traversed along the part to be threaded at a rate per revolution of the work depending upon the lead of the thread. (Common method of cutting screw threads in the engine lathe.)

2) By taking successive cuts with a multiple-point tool or chaser of the type used to some extent in conjunction with the engine lathe and on lathes of the Fox or monitor types.

3) By using a tool of the die class, which usually has four or more multiple-point cutting edges or chasers and generally finishes the thread in one cut or passage of the tool.

4) By a single rotating milling cutter, which forms the thread groove as either the cutter or the work is traversed axially at a rate depending upon the thread lead.

5) By a multiple rotating milling cutter which completes a thread in approximately one revolution of the work.

6) By a multiple rotating cutter which also has a planetary rotating movement about the work which is held stationary. See Planamilling and Planathreading.

7) By a grinding wheel having its edge shaped to conform to the groove of the screw thread.

8) By a multi-edged grinding wheel which, within certain limits as to thread length, will grind the complete thread in practically one revolution of the work.

Internal screw threads, or those in holes, may or may not be produced by the same general method that is applied to external work. There are three commercial methods of importance, namely:

1) By the use of a single-point traversing tool in the engine lathe or a multiple-point chaser in some cases.

2) By means of a tap which, in machine tapping, usually finishes the thread in one cut or passage of the tool.

3) By a rotating milling cutter of either the single or the multiple type.

Dies operated by hand are frequently used for small and medium-sized parts, especially when accuracy as to the lead of the thread and its relation to the screw axis is not essential and comparatively few parts need to be threaded at a time. When a large number of pieces must be threaded, power-driven machines equipped with dies are commonly employed. If the operation is simply that of threading the ends of bolts, studs, rods, etc., a "bolt cutter" would generally be used, but if cutting the thread were only one of several other operations necessary to complete the work, the thread would probably be cut in the same machine performing the additional operations. For instance, parts are threaded in turret lathes and automatic screw machines by means of dies and in conjunction with other operations. When

screws are required which must be accurate as to the pitch or lead of the thread, and be true relative to the axis of the work, a lathe is generally used; lathes are also employed, ordinarily, when the threaded part is comparatively long and large in diameter. Many threads which formerly were cut in the lathe are now produced by the milling process in special thread-milling machines. The method often depends upon the equipment at hand and the number of parts to be threaded. Very precise threads may be produced by grinding.

Taps.—A tap is an internal thread-cutting tool having teeth which conform to the shape of the thread. Taps may be classified according to the kind of thread with which they are provided, as U. S. Standard thread taps, square thread taps, and Acme thread taps, etc. The most important classification of taps, however, is according to their use.

Hand taps: as the name implies, are intended primarily for tapping holes by hand but are often used in machines. All taps used by hand are not termed "hand" taps as there are many special taps used by hand which are known by specific names.

Tapper taps: are used for tapping nuts in tapping machines. They are provided with a long chamfered part on the end of the threaded portion, and a long shank.

Machine nut taps: are also used for tapping nuts in tapping machines. This type is designed for more severe duty than the tapper tap and is especially adapted for tapping holes in materials of tough structure. Machine nut taps are chamfered and relieved in a different manner from tapper taps.

Machine screw taps: may be either hand taps or machine nut taps, but are known by the name "machine screw tap," because they constitute a class of special taps used for tapping holes for standard machine screw sizes.

Screw machine taps: for tapping in the screw machine are provided with shanks fitting either the turret holes of the machine or bushings inserted in these holes. As these taps ordinarily cut threads down to the bottom of the hole, they are provided with a very short chamfer.

Pulley taps: are simply a special type of taps used for tapping holes which cannot be reached by ordinary hand taps, as, for instance, the set-screw or oil-cup holes in the hubs of pulleys. They are simply hand taps with a very long shank.

Die taps: also known as long taper die taps, are used for cutting the thread in a die in a single operation from the blank, and are intended to be followed by a sizing hob tap. Die taps are similar to machine nut taps.

Hob taps: are used for sizing dies. They are intended only for the final finishing of the thread and can only take a slight chip. They are made to the same dimensions as regular hand taps, but fluted differently.

Pipe taps: are used for tapping holes for standard pipe sizes. These taps are taper taps. There is also a special form of pipe tap termed *straight* pipe tap, which is simply a hand corresponding in diameter and number of threads per inch to standard pipe sizes.

Pipe hobs: are similar to pipe taps, but are intended only for sizing pipe dies after the thread has been cut either by a pipe tap or in a lathe.

Boiler taps: are used in steam boiler work where a steam-tight fit is required. They are made either straight or tapered. The straight boiler tap is practically only a hand tap.

Mud or washout taps: are used in boiler or locomotive work. They are sometimes also called arch pipe taps. Patch bolt taps are used in boiler and locomotive work. These are taper taps similar to mud or washout taps.

Staybolt taps: are used on locomotive boiler work. They are usually provided with a reamer portion preceding the threaded part, and have generally a long threaded portion and a long shank. A special form of staybolt tap is known as a spindle staybolt tap which revolves on a central spindle with a taper guide on the front end.

Stove-bolt taps and *carriage-bolt taps* are taps which have derived their names from the uses to which they were originally put. These taps have special forms of threads.

Bit-brace taps differ in no essential from the hand tap on the threaded portion, but are provided with a special shank for use in a bit brace.

Blacksmiths' taper taps are made for general rough threading and are used especially in repair work, where an accurately fitting thread is not required.

Inserted cutter taps may belong to any of the classes mentioned and constitute a separate type only because they are not solid, but have the cutting teeth on blades inserted and held rigidly in a tap body.

Machine Elements

Nordberg Key.—This is a taper key of circular cross-section. This type of key may be used for attaching hand wheels to their shafts or for other similar light work requiring an inexpensive type of key. The Nordberg key has a taper of 1/16 inch per foot. The center of the key hole is located at the joint line between the shaft and hub. A small hole may be drilled first to prevent the larger drill from crowding over into the cast-iron hub. A general rule for determining the size of the key is to make the large key diameter equal to one-fourth the shaft diameter.

Woodruff Keys.—In the Woodruff key system, half-circular disks of steel are used as keys, the half-circular side of the key being inserted into the keyseat. Part of the key projects and enters into a keyway in the part to be keyed to the shaft in the ordinary way. The advantage of this method of keys is that the keyway is easily milled by simply sinking a milling cutter, of the same diameter as the diameter of the stock from which the keys are made, into the shaft. The keys are also very cheaply made, as they are simply cut off from round bar stock and milled apart in the center. Dimensions of Woodruff keys are given in engineering handbooks.

Saddle Key.—This form of key has parallel sides and is curved on its under side to fit the shaft. It is slightly tapered on top so that, when it is driven tightly in place, the shaft is held by frictional resistance. This key should be fitted so that it bears lightly on the sides and heavily between the shaft and hub throughout its entire length. As the drive with this type of key is not positive, it is only used where there is little power to transmit. It is an inexpensive method of keying, as the shaft does not need to be machined.

Locomotive Development.—The first steam locomotive which ever ran on rails was built in 1804 by Richard Trevithick, an Englishman, and the first one to be used on a commercial basis was built by Matthew Murray, another Englishman. In 1811, Blenkinsop of Leeds, had several locomotives built by Murray in order to operate a railway extending from Middletown Colliers to Leeds, a distance of three and one-half miles. Trevithick's impracticable design had a single cylinder only, but Murray used two cylinders which were utilized in driving the same shaft on which cranks were set at right angles an important arrangement common to all modern locomotives. A cog-wheel, or gear, meshing with a continuous rack laid along the road-bed was employed. These locomotives were used daily for years and were examined by George Stephenson when he began his work on locomotive development. Several years after the construction of Murray's locomotives Hedley and Stephenson demonstrated that the gear and rack method of propulsion was unnecessary, and that the frictional resistance of smooth drivers would supply adequate tractive power. Stephenson's name will always be associated with locomotive development owing to his accomplishments in perfecting the locomotive and in establishing it on a commercial basis. His first locomotive was tried on the Killingworth Railway in 1814. The first locomotive to be used in the United States was imported from England in 1829.

Percentages of Radial and Thrust Loads.—There are three types of bearing that are combined load carriers: First, the annular ball bearing, which is primarily designed for radial loads and has no angle of contact incorporated in its design, therefore having minimum thrust capacity (approximately 20 per cent of its radial capacity). Second, the one-direction angular contact bearing, which has a thrust capacity depending upon race design and the angle incorporated, which is generally made so that the thrust capacity is 100 per cent of the radial capacity. (This bearing, however, when used for combined loads, can

only be used in pairs, and must have a threaded or shim adjustment incorporated in the mounting design to allow for initial adjustment.) Third, the double angular type bearing which is really two of the previously mentioned bearings built as a self-contained unit. The functioning of this bearing is not dependent on any exterior adjustment, and the angle of contact is generally such that it will sustain approximately 150 per cent of its radial capacity as thrust.

Roller Bearing.—The load on roller bearings is supported by cylindrical or conical rollers interposed between two races, one race being mounted on the shaft and one other in the bearing proper. There are three principal designs of roller bearings. One is for straight radial loads, the lines of contact of the rollers with the races being parallel with the shaft axis, as shown by the left-hand diagram; another design is for combined radial and thrust loads (See Fig. 3b.). With this design, the rollers are tapering so that the lines of contact of the rollers with the races, and the axis of the rollers, will intersect, if extended, at the same point on the shaft axis. A third design is intended for thrust or axial loads exclusively. Bearings for radial loads may have solid rollers, or the hollow helically-wound type such as is used in the Hyatt bearing. Although anti-friction bearings have replaced a great many plain or sliding bearings, the trend is toward a much wider application, and evidently will include eventually the heaviest classes of service since modern anti-friction bearings not only greatly reduce friction losses, but lower maintenance and repair costs.

Ball Bearing Lubrication.—To obtain the full measure of efficiency and service from ball and roller bearing equipment, the kind and quality of the lubricant, as well as the system of applying it, must be adapted to the design of the bearing, the design of the machine, and the operating conditions.

Operating Temperatures: Under ordinary conditions the temperature of a bearing while running will be from 10 to 60 degrees F. above that of the room. If it exceeds 125 degrees F., ordinary greases will frequently prove unsatisfactory. They will tend to soften and flow continuously into the path of the rolling elements, causing a rise in the normal operating temperature due to the increased frictional resistance introduced. This may eventually result in the separation of the oil and soap base, with a complete loss of lubricating qualities. In some cases, greases developed for use at high temperatures may be employed. Care should be taken, however, to see that they meet all the requirements for adequate lubrication.

Mineral oil of proper physical and chemical properties is an ideal lubricant for ball and roller bearings when the housing is designed to control the quantity entering the bearing and to prevent leakage and protect the bearing from the entrance of foreign matter. A ball or roller bearing should not be subjected to temperature in excess of 300 degrees F., because of the danger of drawing the temper of the hardened steel races and balls.

Quantity of Lubricant Required: In no case does a ball or roller bearing require a large quantity of lubricant. On the contrary, a few drops of oil, or a corresponding amount of grease, properly distributed over the running surfaces of the bearing, will provide satisfactory lubrication for a considerable period of time. A large volume of lubricant within a

bearing will usually result in high operating temperatures, due to the working or churning of the lubricant by the rolling elements and retainer. This may seriously impair the useful life of the lubricant through oxidation or sludging of the oil or actual disintegration of greases.

Use of Grease: If grease is used, the housing should not be kept more than one-fourth to one-half full of the lubricant. Unlike oil, there is no way of controlling with any degree of exactness the quantity of grease in a housing, and greater care must therefore be taken to avoid overloading. A bearing that runs at too high a temperature will often return to normal temperature if some of the lubricating grease is removed.

Grease is being used successfully for the lubrication of ball bearings at high speeds, but great care is necessary, both from the standpoint of housing design and selection of the lubricant, in order to obtain satisfactory results. Any system employed must be designed to feed only a limited amount of grease to the bearing. For the average application at operating speeds up to 3600 revolutions per minute, a grease of soft consistency, such as a No. 2 grease, will usually be found satisfactory, provided it is suitable in other respects. Hard greases, such as No. 3, may be used if the grease is to serve as a packing medium around the shaft to prevent the entrance of dirt, water, or other corrosive substances.

Sealed Bearings: Bearings for certain classes of service must operate over long periods without relubrication, as, for example, a motor installation on an airplane beacon; hence the efforts of ball-bearing manufacturers to produce bearings so completely sealed as to enable them to retain their original charge of grease for many months. In appreciation of this requirement, the petroleum industry has developed lubricants that will maintain lubrication for a long period without change in structure, homogeneity, lubricating properties, or leakage.

Engine Governors.—Governors may be of a purely centrifugal type such as the fly-ball or pendulum design previously referred to, or the principle of inertia may be introduced to secure better speed regulation. Thus, there are two general classes of governors known as centrifugal and inertia governors. The method of utilizing the motion of the governing element for regulating the speed varies; as applied to steam engines, there is the general type of governor which controls the speed by operating a throttling valve which increases or diminishes the amount of steam admitted to the steam-chest, and another general type which regulates the speed by changing the point of cut-off and consequently the amount of expansion in the cylinders.

In the design of governors, the sensitiveness, effort, and stability of the governor are important factors. The sensitiveness of a fly-ball governor is indicated by the amount that the governing sleeve is displaced for a given change in speed, the displacement being relatively large for a given speed change if the governor is sensitive.

The term "effort" as applied to a governor relates to the energy it is capable of exerting upon the governing mechanism. Thus, in the case of a fly-ball governor, the effort indicates the energy exerted on the sleeve while the governor speed is increasing or diminishing. If the energy stored in a revolving governor is small, its sensitiveness will be reduced, because a larger speed change is necessary to obtain the power for operating the governing mechanism than would be required with a governor which exerts greater energy for a given speed change.

When a governor occupies a definite position of equilibrium for any speed within the range of speeds controlled by the governor, it is said to be "stable." If the load on an engine having a fly-ball governor is diminished, the balls of a stable governor will move outward to a new position as the speed increases, although there will usually be a temporary oscillating movement on each side of this new position, the oscillations gradually diminishing. If the governor were unstable (and therefore useless) the oscillations would increase until the limiting points were reached.

Fig. 1.

Fig. 2.

Loaded or Weighted Fly-ball Governors.—As the arms of a governor of the conical pendulum type swing outward toward the horizontal position as the result of increasing speed, the change in height h (see Fig. 1) is small for given changes in speed. For instance, if the speed is changed from 50 to 70 revolutions per minute, the difference between the values of h is nearly 7 inches, whereas if the speed changes from 200 to 300 revolutions per minute, the difference in height h for the two speeds is only about $\frac{1}{2}$ inch. Hence, the simple pendulum governor is not suitable for the higher speeds, because then the movement which accompanies the speed changes is too small to secure proper regulation through the governing mechanism. Fly-ball governors are adapted for much higher speeds by loading them. The load may be in the form of a weight which surrounds the spindle, as illustrated by Fig. 1. This is known as a Porter governor.

In the following formula, w = the weight of one governor ball in pounds; c = the weight of the additional load; h = the height in feet indicated by the diagram, Fig. 1; n = speed of governor in revolutions per minute:

$$h = \frac{2933}{n^2} \times \frac{e + w}{w}$$

If the governor is constructed as indicated by the diagram Fig. 2, the height h is not measured from the points at which the arms or rods are suspended, but from the point where the axes of the rods intersect with the vertical center line. The outward movement of the balls may be resisted by a spring instead of a weight, as in the case of the Hartnell governor, which is known as a spring-loaded type.

Sensitiveness and Stability of Governors.—The sensitiveness of one governor may be compared with that of another by determining the *coefficient of speed variations*. If C = the coefficient of speed variations, M = maximum speed within limits of the governor action; M_1 = minimum speed within limits of governor action; m = mean speed within these limits; then,

$$C = \frac{M - M_1}{m}$$

The minimum value of coefficient C necessary to obtain stability in a pendulum type of governor is given by the following formula in which y = distance the fly-balls move horizontally in feet; F = mean centrifugal force of fly-balls in pounds; H = indicated horsepower of engine; W = the weight of engine flywheel in pounds; S = revolutions per minute of main shaft; R = the flywheel radius in feet.

ROPE SPLICING

$$C = 4000 \sqrt[3]{\frac{xy}{F}} \times 8 \sqrt[4]{\frac{H^2}{S^4 R^4 W^2}}$$

The factor x in this formula represents that weight which would be equivalent to the weights of the various moving parts, if it were centered at a point corresponding to the center of gravity of the fly-balls. To determine the value of x , first determine the weights of the different moving parts of the governor, such as the balls, the central weight or load (in the case of a Porter governor), the sleeve, etc.; multiply the weight of each part by the square of the distance it moves from one position to the other; add the various products thus obtained, and divide the total sum by the square of the corresponding movement of the fly-balls at right angles to the governor spindle.

Shaft Governors.—Shaft governors are so named because the governing mechanism is carried by the main shaft and is commonly attached in some way to the flywheel. One type is so arranged that, in the case of a steam engine, the action of centrifugal force on a pivoted and weighted lever, to which a spring is attached, changes the position of the eccentric which operates the slide valve, thus increasing or decreasing the valve travel and changing the point of cut-off. Another type is so designed that the inertia of a pivoted “weight arm” accelerates the governing action by acting in conjunction with the effect of centrifugal force, thus increasing the sensitiveness of the governor. With the inertia governor, the effort or force needed to actuate the governing mechanism increases as the rate of velocity change increases; hence this type is adapted to engines liable to sudden load changes. When the load remains practically constant, the centrifugal type of shaft governor is often employed in preference to the inertia type. The design of these governors depends upon the arrangement of the governing mechanism and upon varying factors.

Rope Splicing.—Splicing is the operation when two pieces of rope are joined by unlaying the strands and weaving or intertwining the strands of one end with those of the other.

Short Splice: The first step in making a short splice is to unlay or untwist the strands at the end of each rope. After the ropes are placed together, as shown at A, Fig. 1a, the strands on one side, as shown at d , e , and f , are either held together by the left hand or are fastened together with twine, in case the rope is too large to be held by the hand. The splicing operation is started by taking one of the strands as at a , and passing it across or over the adjacent strand d and then under the next strand e , after having made an opening beneath strand e . The strands b and c are next treated in the same manner, first one and then the other being passed over its adjoining strand and then under the next successive one. These same operations are then repeated for the strands d , e and f of the other rope. The splice will now appear as shown at B, Fig. 1b. In order to make it stronger and more secure, the projecting strands of each rope are again passed diagonally over the adjoining strands and under the next successive ones. The splice should then be subjected to a strong pull, in order to tighten the strands and make them more compact. The projecting ends of the strands should then be cut off, thus completing the splice as shown at C. For making the openings beneath the strands on the rope, what is known as a marlin spike is generally used. This is merely a tapering, pointed pin made of wood or iron.

Fig. 1a. Method of Making a Short Splice

Fig. 1b. Method of Making a Short Splice

Fig. 1c. Method of Making a Short Splice

Long Splice: When a rope has to pass through pulley blocks, or in case any increase in the size of the rope would be objectionable, the short splice is not suitable and the long splice should be employed. The diameter of a long splice is the same as that of the rope and, if the work is done carefully, the place where the ends are joined can scarcely be distinguished from the rest of the rope. The ends of each rope are first unlaied or untwisted the same as when making a short splice, but for a distance about three times as long. These ends are then placed together so that each strand lies between two strands of the other rope, the same as for a short splice. One of the strands is next unlaied and then a strand from the other rope is curled around into the groove thus made, as indicated at A Fig. 2a, strand a having been unlaied and strand b from the other rope end, put into its place. Care should be taken to twist strand b so that it will lie in its natural position into the groove previously occupied by strand a, as the neatness of the splice will depend partly upon the care with which this part of the work is done. This operation is then repeated in connection with strands c and d, strand c being unlaied and strand d twisted around to occupy the groove thus made. The splice will now be as shown at B, Fig. 2b, and the next step is that of disposing of the protruding ends of the strands. After these strands have been cut to about the length shown at B, two of the strands, as at a and b, are first reduced in size by removing about one-third of the fiber; these ends are then tied by an overhand knot as shown at e. After tightening this knot, the protruding ends may be disposed of the same as when making a short splice, or by passing them over the adjoining strand and through the rope, under the next one. By gradually removing the fiber each time the end is passed across an adjoining strand, the enlargement of the rope at this point may be made very slight and scarcely noticeable. The strands f and g which remain in their original positions in the center of the splice, and the strands c and d are disposed of in a similar manner, thus completing the splice as shown at Fig. 2c.

Fig. 2a. How a Long Splice is Made

Fig. 2b. How a Long Splice is Made

Fig. 2c. How a Long Splice is Made

Eye-Splice: When a loop is formed at the end of a rope by splicing the free end to the main or standing part of the rope, this is known as an *eye-splice*. The end of the rope is first unlaidd about as far as it would be for making a short splice. After bending the end around to form a loop of the required size, the middle strand *a*, Fig. 3a, is tucked under a strand on the main part of the rope. The strand *b* is next inserted from the rear side under the strand on the main part which is just above the strand under which *a* was inserted. Since strand *b* is pushed under the strand on the main part from the rear side, it will come out at the point where strand *a* went in, as Fig. 3b. The third strand *c* is now passed over the strand under which strand *a* was inserted, and then under the next successive one, as Fig. 3c. These three strands are next pulled taut and then about one-third of the fiber should be cut from them; they are next tucked away by passing a strand over its adjoining one and under the next successive strand. Cutting away part of the fiber or yarns is to reduce the size of the splice and give it a neater appearance. By gradually thinning out the fiber, the over-lapping strands may be given a gradual taper, as Fig. 3d which shows the completed eye-splice.
